1907.

[Cd. 3758.]

PREFACE.

The details and results of the experiments made to determine the relative virulence and pathogenic effects of tuberculous viruses of Bovine and Human origin on various species of animals have been published in the first and second volumes of the Appendix to the Second Interim Report of the Commission.

Whilst those experiments were in progress others, undertaken to throw light on collateral questions, were undertaken at Stansted, and the results of these additional investigations are collected together in this volume.

The results of ten separate investigations are included. Each of these was designed by, and carried out under the direct supervision of, the Commission, but the actual reports have been written by the investigators whose names are attached to them. In their own report (Part I.) the Commission expressed the opinions they themselves had founded on the results of the whole of the experimental work carried out at Stansted, and these general opinions were in every instance in complete accord with those of the resident investigators. In the individual reports contained in this volume it has been considered right to allow each of the investigators to set forth not only the definite facts arising out of the experimental work, but also his own views based on the work done by himself. (Report, Part I., page 42.)

THE CULTURAL CHARACTERS OF THE BOVINE TUBERCLE BACILLUS.

Dr. A. STANLEY GRIFFITH and Dr. F. GRIFFITH.

THE CULTURAL CHARACTERS OF THE BOVINE TUBERCLE BACILLUS.

This report gives the results of the investigation as to the cultural characters of the bovine tubercle bacillus.

The investigation has been carried out with two chief objects in view:

1. To find the most favourable media for the growth of the tubercle bacillus.

2. To contrast the cultural characters of different strains of bovine tubercle bacilli.

The cultures investigated were derived from bovine animals naturally infected with tuberculosis, and were isolated, in the majority of cases, direct from the original material.

300 strains of tubercle bacilli have been isolated, representing 30 viruses.*

Failures to get the bacillus to grow have been very few and occurred in the early part only, in the cases of a few guinea-pigs where either unsuitable media were used or an insufficient number of tubes sown.

The following is a list of the media used:—

Serum media. Serum has been obtained from 12 species of animals, namely, the ox (cow and calf), horse, pig, goat, sheep, baboon, monkey, lemur, dog, cat, rabbit, and guinea-pig.

Glycerin serum.

Serum agar, with and without glycerin.

Egg: the yolk and white have been used separately and combined.

Glycerin agar.

Glycerinated potato.

Glycerin broth.

ditto. with 10 per cent. gelatine.

Asparagin liquid medium.

Mode of Preparation of Media.

Serum media: The serum media are prepared in the following way: Blood is collected in sterile flasks from animals, either by inserting a cannula in the external jugular vein during life, or in the common carotid artery after shooting, or anæsthetising; the blood of rabbits and guinea-pigs is usually collected by allowing the blood to flow direct into a large sterile test-tube pressed against the side of the neck after exposing and severing the carotid and jugular vessels.

The blood is allowed to stand from one to three or four days, according to the speed with which the serum separates; the serum is then decanted, either by means of a pipette or a syphon, and distributed into tubes, about 6 cc. being used for each. The tubes are put in an inclined position in a serum inspissator, and kept for about two hours at a temperature that varies in different cases between 75°C. and 80°C. In the inspissator is placed a bowl containing water. Each tube is then sealed with paraffin and stored.

By this method the different kinds of sera, at the time of inoculation, necessarily varied in age and moistness.

To make the media more strictly comparable, the serum after distribution into test tubes was at one period fractionally sterilised (*i.e.* kept at 60°C. for an hour on five consecutive days) and stored in a liquid state in an ice chest, each tube having a rubber cap placed over its aperture to prevent evaporation. When required for use a series of tubes were coagulated as above. In this way it was thought that variations in the physical characters of the serum, produced by slight differences in the temperature and duration of the coagulation, and in the amount of moisture, would be eliminated.

The method was abandoned because it did not appear to possess enough advantage over the old way of preparing the serum to make it worth the extra trouble; there was the distinct disadvantage that the tubes were never ready for immediate sowing and, probably on account of the concentration of the serum, a greater tendency to the formation of a film of salts on the surface was exhibited.

Glycerin serum: 5% sterile glycerin is added to a measured quantity of serum before distribution into tubes; the procedure is then the same as for serum.

Serum agar is prepared by adding 0·5 cc. serum to 5 cc. agar liquefied and cooled down to about 50°C.; the two are well mixed and sloped.

Egg mixture: fresh eggs are broken into a sterile beaker and the white and yolk beaten up with a sterile glass rod; sterile salt solution is then added in the proportion of 1 to 3 and the mixture is distributed into tubes; the tubes are sloped in the serum inspissator and kept for 2 hours at 75°C. on two consecutive days.

The yolk and white, when used separately, are coagulated in the same way as the egg mixture; no saline is added.

Yolk agar is made in the same way as serum agar.

Glycerinated potato: the potato wedges are first soaked in a 1 in 1000 sodium carbonate solution for 24 hours and then in a 5 % glycerin solution deeply tinted with litmus until the potato acquires a definite blue colour. The potato is afterwards put into test tubes containing at the bottom a little cotton wool soaked in 5 % glycerin solution and sterilized in the usual way. Growth is readily observed on a potato tinted in this manner.

Glycerin agar, and glycerin broth are prepared after the usual formulae.

The asparagin medium was prepared by dissolving asparagin (5 grms.), KH_2PO_4 (5 grms.), sodium chloride (5 grms.), magnesium citrate (2·5 grms.), potassium sulphates (2·5 grms.), in distilled water to 1000 cc. and filtering the solution after reducing the acidity to 20 per litre.

Source of Cultures.

In the case of the viruses the direct culture has usually been obtained from the thoracic glands and occasionally from the lung, mesenteric glands or perlsucht growths on pleura or diaphragm.

In experimental bovines the material for inoculating the tubes has been taken from the prescapular, mesenteric thoracic or supramammary lymphatic glands, the prescapular gland being most often used.

In pigs the direct cultures have been raised from the submaxillary and bronchial glands.

In the guinea-pig the sternal gland is the most convenient gland from which to make cultures, but when the sternal gland is not much enlarged, the liver or the spleen has been chosen on account of the softness of the tissues of these organs.

The lesions in a monkey, rabbit or mouse are well adapted for the production of cultures; they are usually not only rich in bacilli, particularly in the latter animal, but also, being softened, easy to emulsify and spread evenly over the surface of the medium.

Method of Raising Primary Cultures.

Whatever organ or gland is selected it is first freed from all surrounding connective tissue, dried and then well seared with a Paquelin cautery. An incision is made with a sterile knife in the centre of the seared area, and a small piece of tissue is removed.

In the early part of the work a bit of the tissue was deposited on the surface of each medium, and was then picked up with a stout platinum wire and carried to the condensation water at the foot of the slope; here it was squeezed and pressed against the sides of the tube until the water became definitely milky; the emulsion thus found was allowed, by slightly inverting the tube, to flow over the whole surface and the broken up pieces of tissue were well rubbed over every part of the medium.

When caseous and softened lesions were being dealt with an even distribution of the material was readily secured, but when the tissue was composed of the firm, dense, caseo-necrotic material met with in acute tuberculosis in bovines a good distribution was not so readily effected.

In such cases various modifications were tried; at first pieces of the gland were broken up in a sterile mortar and emulsified with normal saline, a loopful of the emulsion being smeared over the surface of each

* Virus is the term applied to the original material; a culture derived from that virus, either directly or through an experimental animal, is called a "strain."

medium. Then, instead of in a mortar, the piece of tissue was broken up and emulsified in a short stout test tube by means of a glass rod.

The last method, the one now exclusively used, has several advantages; a small piece of tissue which in the first method could be used for one tube only, can by this means be used to inoculate a large series and there are fewer risks of air-borne contaminations than when emulsified in a mortar; there is also the advantage that the emulsion so prepared can be examined microscopically before sowing the tubes, and if too rich in bacilli, *e.g.* for the production of discrete colonies, can be diluted to any required extent, or if too poor a larger loop can be used for sowing the tubes.

After sowing, the tubes are resealed with paraffin and placed in the incubator in a vertical position. At one time, to prevent undue evaporation the tubes were placed in a position inclined so as to allow the water of condensation to flow over the greater part of the surface of the medium.

The practice was discontinued for primary cultures, because it was found that this position enabled contaminating organisms which, in the vertical position might have remained localised to one spot, to overrun the whole surface, thus rendering it impossible to secure a pure culture.

Estimation of the Value of Various Media for Primary Cultures.

Many observers have experienced difficulty in raising cultures of the bovine tubercle bacillus on ordinary media. This investigation has been carried out to find what media are most suitable for the growth of the bacillus in primary culture and incidentally to ascertain whether the serum of different species of animals has any specific value. For this purpose whenever a culture was desired a series composed of as large a variety of media as was available at the time was sown. The results are given in tabular form.

Medium.	Number of tubes sown.	Number of Positive Results.	Percentage.	Medium.	Number of tubes sown.	Number of Positive Results.	Percentage.

The egg medium has been the most successful and can always be relied upon for the production of primary cultures. It has the additional advantages of being readily obtained and easily prepared. The yolk and the egg mixture are of about equal value and far superior to the white alone.

On the first three media the colonies are visible in from eight to twelve days and appear as transparent points. If very numerous they remain small and transparent, but when there are only a few they may grow to a considerable size becoming raised and creamy white, and either moist, or dry and warty.

The sera of different species of animals have been found, as Professor MacFadyean predicted, to vary less than the sera of animals of the same species. The sera of a large number of animals of each species have been used and at least one serum of each species has given a high percentage of successes. The serum from the cat has been found the most uniformly good, while that of the horse up to the present has been generally poor. Several poor sera in the case of the dog have considerably lowered the high percentage of successes obtained at first. From the calf only occasionally has a good serum been obtained; the adult ox, on the other hand, has yielded a serum which has been invariably good, especially when of a golden yellow colour. In several instances serum containing a large number of blood corpuscles has given better results than the same serum without corpuscles.

The failure to produce growth in the case of some sera appears often to be due to the formation of a film over the surface. It was chiefly to avoid this disadvantage that serum agar was used.

Serum agar is a satisfactory and economical substitute for pure serum, and has the advantage of being perfectly transparent; it has been found to be very little inferior to the egg medium for raising primary cultures.

On several occasions a serum which has been found

poor when coagulated, has given excellent results as serum agar.

Glycerin serum and potato are not very useful for primary cultures and when growth occurs the bacillus is usually one which grows well on glycerinated media in subculture. On potato in one instance a most luxuriant primary growth was obtained, much superior to any subculture on this medium.

On glycerin agar in only a few instances has a primary culture been obtained.

Subcultures.

The tubercle bacillus having once started to grow on artificial media grows readily when transplanted on almost every variety of serum media although early generations grow less abundantly than later. Growth takes place from the outset and usually attains its maximum at the end of three weeks' incubation. On the same variety of serum all the viruses produce the same type of growth. On bovine serum the growth is in the form of a dry, usually uniform grey coherent layer; on dog serum it is moist and more easily emulsified and exhibits no tendency to spread over the condensation water; on pig serum the growth is scaly and more abundant than on bovine serum.

On different varieties of serum the amount of growth varies, being most abundant on those which give the best results in primary culture. The egg medium is unsatisfactory for subcultures.

The bovine tubercle bacillus will not grow at a temperature of 42°C. or when placed under anaerobic conditions.

The bacillus retains its vitality in culture for a considerable time and by means of the egg medium a growth was obtained from a subculture 597 days old (the virulence of this culture for rabbits remained unaltered.)

Comparison of the Cultural Characters of the Different Viruses.

In these comparisons the importance of employing the same technique throughout was recognised, and the following method adopted.

A small amount of culture, approximately equal in all cases, was taken and smeared evenly over the surface of each medium; the even distribution was effected by emulsifying the material on the surface of the medium with a drop of the condensation water. By the use of a small amount of culture, the differences between the various strains are brought out more clearly than when a large amount is used. The most uniform results are obtained when the inoculated material is taken from a vigorous subculture.

The media used for the comparisons of the growth characters have been serum and glycerin serum, glycerin agar, glycerinated potato, and glycerin broth.

On glycerin serum the viruses of bovine origin exhibit three types of growth.

In the first, no growth can be observed until the second or third week, when discrete colonies make their appearance. In some cases the colonies remain small and discrete, in others they continue to grow, and the amount of growth at the end of six weeks may equal or exceed that on the corresponding pure serum. In this first series, the distinguishing features are the initial delay on glycerin serum compared with the steady uniform increase on pure serum, and the absence of any considerable variation between the strains which exhibit this type of growth.

In the second, growth takes place from the outset and up to the end of the second week is similar in appearance to that on serum alone, and about equal in amount. The amount of growth finally produced at the end of the third or fourth week varies in different strains; with Viruses II., VII., XXIX., and XXX. growth is about equal to that on pure serum, with Virus XVI. rather less, and with Viruses VIII., XIV., XX., XXII., XXIII., and XXVII. rather more than on the corresponding serum.

In the third, growth during the first week is more abundant than on pure serum, and progressively increases, becoming, at the end of the fourth week, from two to four times as much as on serum. The characters of the growth also differ markedly on the two media; that on serum is grey and uniform with, in many cases, scattered raised colonies on the surface, while that on glycerin serum is whiter and moister with a more irregular and often wrinkled surface.

The bovine viruses which exhibit the first type of growth are Nos. I., III., IV., VI., XII., XIII., XV. XVII., XVIII., XIX., XXI., XXIV., and XXVI.

Those which exhibit the second type are II., VII., VIII., XIV., XVI., XX., XXII., XXIII., XXVII., XXIX., and XXX.

Those which exhibit the third type are V., IX., X., XI., XXV., and XXVIII., the latter growing rather less well than the others.

On pure serum the characters of the growth are the same for all viruses, and no differentiation on this medium can be made after they have been in cultivation some time. A uniform grey layer, often with raised white colonies on the surface, is formed at the end of the first week; this increases until the third week, when in the majority of cases growth ceases.

Viruses of Class I. do, however, grow in early generations less readily on serum than those of Class III., thus showing that the differences between the various viruses brought out by the use of glycerinated media are differences in saprophytic power and are in freshly isolated cultures capable of demonstration on pure serum.

On glycerin agar the results are in accordance with those on glycerin serum, and the same differentiation of the viruses can be made.

The first series of viruses grows with difficulty; in some cases no growth whatever occurs, in others discrete colonies make their appearance after several weeks, sometimes in the fourth, and often much later. As in the case of glycerin serum, there is the initial delay before the appearance of colonies, which when numerous may coalesce to form a thin continuous layer, and when fewer and discrete may attain a considerable size, becoming heaped up, warty, and slightly pigmented.

In the second series growth takes place from the outset, a thin grey layer being formed at the end of the first week, which increases slightly up to the end of the third week. Subsequently, in some cases, raised colonies develop on the surface.

In the third, growth is more abundant, and attains a moderate thickness at the end of the third week, showing in some cases a fine wrinkling on the under-surface but no pigmentation. In the case of Virus V., however, a definitely wrinkled and slightly pigmented layer was obtained.

On glycerinated potato growth is very variable, but in the main corresponds with that on glycerin agar. The viruses in the first and second series form after many weeks discrete colonies, which grow slowly becoming pearly-white and up to a pinhead in size. Occasionally larger, irregular, creamy nodules are obtained after several months. Those in the third series grow more readily, and produce in from two to three weeks a grey layer, varying in thickness, in which raised warty yellowish colonies may subsequently develop. The growth of viruses in all the series may be attended with the formation of pigment to some extent, varying from creamy white to a definite yellow.

On glycerin broth great difficulty was experienced in getting many of the viruses to grow when inoculated direct from serum. This has been especially the case with viruses in the first series, the inoculated material either not increasing or forming warty nodules, which might, after many weeks, send out over the surface a very thin grey membrane.

On the asparagin medium, growth was as a rule more readily obtained than on broth, but the pellicle formed was often incomplete and in all cases thin and uniform. As all the viruses produced more or less the same type of pellicle, little differentiation was exhibited on this medium.

Various devices have been adopted to enable the inoculated material to form a pellicle on the surface. In one the broth in six-ounce medicine bottles, contained a pledget of cotton wool which just projected above the surface of the fluid, and on to which the culture was inoculated. Growth took place on the wool in the form of white or creamy irregular nodules from which after a long time a delicate grey pellicle developed.

In another, 10 per cent. gelatine was added to the broth forming at 37°C. a liquid medium. This medium gives uniform results since, being solid at room temperature it can be inoculated from young serum cultures of equal ages; it has the additional advantage, that by allowing it to solidify and adding formalin the pellicles can be preserved as permanent specimens. The characters of the growth do not differ from those of glycerin broth cultures.

The method devised by Dr. Eastwood of combining solidified serum and broth has also been attended by

constant results in producing surface growths characteristic of the different viruses.

Those viruses which grow with most difficulty on glycerinated media show a corresponding reluctance to grow on the surface of glycerin broth; the type of pellicle formed is delicate grey and almost transparent, and the growth is occasionally broken up into islands which incompletely cover the surface.

Viruses which grow more readily on glycerinated media generally grow more rapidly on broth, and produce a thicker translucent pellicle with opaque patches. In all cases, after the pellicle has begun to form, the surface of the broth is quickly covered, and there is little subsequent thickening, the growth often showing a tendency to break up, become moist and sink.

A consideration of the results on the differential media shows that bovine bacilli can be arranged in a more or less complete series beginning with a bacillus which grows badly on all the differential media and ending with one which grows relatively well. On this point we are in entire agreement with Dr. Eastwood in his classification. We have not, however, attempted to arrange the strains in a consecutive series; our experience with various culture media makes us hesitate to rely too much upon small points of difference.

Nevertheless, there is a marked contrast between the extreme types of growth on all media containing glycerin. For example, a comparison of the weight of growth produced on serum and glycerin serum, respectively, has been made with strains representing each series.

The method adopted was to sow in each case a number of tubes of serum and glycerin serum and incubate for three weeks. An equal number of tubes on which the best growths had occurred was then selected and the growth scraped off and weighed. In the case of Virus 20 the growth after being weighed directly was emulsified with saline and estimated by the volumetric method devised for culture inoculations. The weight as estimated by this method was found to agree closely with that obtained on the balance.

TABLE OF COMPARISONS OF WEIGHTS.

Virus.	Number of tubes on each medium.	Weight on Serum.	Weight on Glycerin Serum.	Ratio.
B. IV.	4	53	5	10 : 1
B. XX.	4	100	120	1 : 1·2
B. V.	6	90	300	1 : 3·3
B. IX.	4	35	142	1 : 4

In the above comparisons the same serum of excellent quality was employed. When only a moderate serum is used the differences are more marked, as in the following cases which were incubated for 4 weeks.

B. X. G.P. 1072	1	4	47	1 : 11
B. X. G.P. 1070	1	14	45	1 : 3
B. XIV.	1	12	40	1 : 3·3

The following belong to the most difficult growing viruses, and would yield a result similar to Virus 4. The comparison shows their increased luxuriance on glycerin serum after growing for a few generations on that medium.

B. XVIII.	1	17	27	1 : 1·6
B. XII.	1	5	10	1 : 2

A. STANLEY GRIFFITH.
F. GRIFFITH.

DESCRIPTION OF THE CHARACTERS OF THE VIRUSES ON THE DIFFERENTIAL MEDIA.

Bovine Viruses.

Virus B. I.

Mediastinal Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Cow 44	17th	Moderately thick uniform grey layer.	No growth occurred until the end of the 2nd week, when a few minute colonies appeared. At the end of the 3rd week the colonies were more numerous but discrete. At the end of the 4th week the colonies had coalesced and covered the whole surface with a grey layer.	The final pellicle was thin uniform grey and semi-transparent with fine whitish lines. After several broth subcultures a rather thicker translucent pellicle with fine wrinkling was formed.	No growth was visible during the first 3 weeks. At the end of the 4th week there were very numerous minute discrete grey colonies scattered over the surface. These increased in size, forming thin grey filmy colonies, some with opaque central foci; these subsequently coalesced in patches.	At the end of 3 weeks minute grey points were seen with a hand lens. In 10 weeks there were moderately numerous small raised colonies of various sizes.

Other strains of this virus—G.P. 14, Cow 40, Calf 106, Baboon 66, Pig 16, Pig 96, and Pig 98—which were tested on the differential media, closely resembled Cow 44.

In the culture obtained from Baboon 8, fed with the milk of Cow 64 (Virus I.), a decided increase of luxuriance has resulted. This increase was maintained after passage through a second baboon (No. 64).

Virus B. II.

Lung.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Heifer 66.	13th	Uniform grey layer with a few raised white colonies.	Growth at the end of 4 weeks was equal to that on pure serum. There was no difference in character with the exception that the small white colonies on the surface were more raised and numerous.	The culture from Heifer 66 was not grown on broth, but in four other strains of this virus the type of pellicle was identical. That from Heifer 100 is described. Growth was slow in beginning: in 3 weeks there was one delicate grey island. In 5 weeks the surface was covered with a delicate grey transparent pellicle composed of small islands speckled with opaque greyish-white foci. In 8 weeks all the growth had sunk.	At the end of the second week there was a thin uniform grey layer with numerous small raised colonies superimposed. A slight increase was noted at the end of the 4th week after which there was no further change.	Very minute discrete greyish-white colonies were first visible at the end of the 4th week. These increased to a very slight extent subsequently.

Cultures raised from six other strains of this virus: Bull 22, Heifer 100, Calf 134, Calf 178, Guinea-pigs 537, 172, 1322 and 1735 agreed very closely in cultural characters with that isolated from Heifer 66.

Guinea-pig 1735 was the 24th of a series of guinea-pigs the first of which was inoculated with the original material of Virus II. The virus was kept going in guinea-pigs to see if any modification by prolonged residence in these animals could be produced. The result showed not the least change in cultural characters.

Virus B. III.

Mediastinal Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct.	15th.	Uniform grey layer of moderate thickness.	There was no growth during the first 2 weeks. At the end of the 3rd week the surface was covered with minute grey colonies. These increased a little in size but remained discrete.	No growth has been obtained on broth. On glycerin gelatine the surface became covered with transparent filmy islands. On an asparagin medium (2 per cent. glycerin) two-thirds of the surface was covered with a delitate grey pellicle in 7 weeks.	At the end of 5 weeks there was no growth. In 10 weeks there were two flat grey colonies with opaque centres.	In 4 weeks there were two minute grey colonies. These increased to four in the 5th week. In 10 weeks the four colonies were rather less than a pin-head in size, creamy in colour and surrounded by a group of very minute grey colonies.

Two other strains of this virus, Monkey 64 and Calf 214, have been investigated, and gave similar results, except that more numerous colonies appeared on glycerin agar in the case of Monkey 64.

Virus B. IV.

Mesenteric Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct.	29th.	Uniform layer of moderate thickness in 3 weeks, with numerous raised white colonies.	In 14 days there was no growth. At the end of 3 weeks the surface was covered with numerous minute grey and greyish white colonies. In the fourth week these coalesced and formed a complete layer, covered with raised white colonies. This increased to a moderate thickness in the sixth week and appeared almost equal in amount to that on serum alone.	On serum and broth, no pellicle was formed at the end of 5 weeks; there were several small yellowish nodules floating on the surface. After subculture for several generations on gelatine broth, a growth was obtained on transference to broth. The type of pellicle produced was thin grey and translucent, with delicate wavy whitish lines.	No growth was obtained with this generation of culture. Several other attempts on different agar media with earlier generations also failed to produce growths.	At the end of 3 weeks minute grey points were seen, which in 3 months showed no change. An earlier generation (17th) showed half-a-dozen opaque white granules at the end of 8 weeks. At the end of 3 months there were 26 colonies of all sizes up to that of a pin-head, slightly creamy in colour.

Cultures of this virus were isolated after passage through different species of animals, namely, Chimpanzees, 4. 6. 8. 10. 16. Baboons, 22. 30. 50. 62. Dogs, 26. 54. 56. and 74. Cat, 12. Rabbit, 5. Calf, 142. Cow, 172. The results on the differential media with these strains closely resembled the above: the only difference was that some of the strains produced discrete colonies on glycerin agar after several weeks. The culture from Dog 18 was quite different from the original virus.

Dog 18.	5th. Broth 6th and 7th.	Thin uniform layer at the end of 3 weeks.	At the end of the first week there was a uniform layer thicker than on serum alone. In the second week it was twice as thick and at the end of the fourth week there was a very thick opaque white finely wrinkled growth.	A bottle of broth sown with the pellicle from the condensation water of a serum tube, showed a single opaque white island in 4 weeks. This was subcultured on broth and in 4 weeks there was a thick opaque white, slightly wrinkled pellicle, covering about a quarter of the surface; growth then ceased.	At the end of the second week, there was a uniform grey layer slightly wrinkled. In the fifth week this had become thick and opaque with well-marked wrinkling of the surface.	In 2 weeks, there was a greyish growth composed of very minute colonies closely aggregated. These increased, becoming slightly yellow and at the end of the seventh week there was a raised opaque granular layer of a yellow colour.

Virus B. V.

Mesenteric Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Heifer 80	12th Broth 19th	Uniform layer of moderate thickness at the end of 3 weeks.	At the end of the 1st week there was a moderately thick grey layer rather better than on serum alone. During the 2nd week the growth became thicker and covered with small white elevated colonies. Growth continued during the 3rd week, the colonies increasing in size. At the end of the 6th week there was a thick greyish white layer, better than on serum, with a moist roughened surface and a slightly wrinkled margin.	In 14 days the surface was covered with a thin uniform translucent grey pellicle already with a tendency to sink.	There was a uniform grey layer at the end of the 1st week. Steady increase took place until the end of the 5th week, when the surface was covered with a grey ground glass layer with fine wrinkling round the edges. At the end of 8 weeks there was very little further increase.	Growth was visible in 11 days as numerous minute grey colonies. In the 5th week there was a layer composed of minute grey colonies. At the end of the 7th week a slight increase was indicated by a few of the colonies becoming a little larger than the rest, being white and slightly raised. No further progress was noticed.

Cultures were also isolated from G.P.'s 711 and 812 inoculated with the original material and were similar to Heifer 80. On 5 per cent. glycerin broth with G.P. 812, the surface was covered in 14 days with a grey translucent pellicle, dotted over with opaque white foci and several warty nodules.

Virus B. VI.

Mediastinal Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	14th.	Uniform layer of moderate thickness in 3 weeks.	No growth was evident until the 3rd week, when the surface was covered with minute grey colonies coalescing in parts. At the 6th week the colonies had fused together, forming an almost continuous thin grey layer.	In 7 weeks there were numerous small grey islands over the surface and a circular patch one and a half inches in diameter rather thicker and speckled with white foci. The growth subsequently sank.	No change was observed until the 6th week, when two minute white colonies were seen. There was no increase at the end of 12 weeks. In the 18th generation no growth could be seen at the end of 4 weeks.	One minute greyish white colony was seen at the end of the 5th week. A few more appeared in the 6th week. 7th week no change.
G.P.1015 (Inoculated with original material)	7th.	Uniform layer.	Uniform layer in 3 weeks identical with that on pure serum.	No growth was obtained.	At the end of the 2nd week there were small sparsely scattered discrete granular colonies. Over part of the surface a thin grey growth developed in between the colonies. At the end of the 11th week there was this patchy grey layer not increased in thickness and numerous small colonies with grey filmy margins.	In the 2nd week there were a few whitish colonies, increasing slightly up to the 5th week. At the end of the 12th week the surface was almost covered with minute pearly-white colonies.

A culture isolated from Calf 216 resembled the direct culture.

Cultures were also obtained from G.P.'s. 1014 and 1015 inoculated with original material; both of these grew distinctly better than the direct culture and were identical with each other. A culture obtained from Calf 240 inoculated with culture of G.P. 1015 had the same characters as the original G.P. cultures.

Virus B. VII.
Mesenteric Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	12th	Uniform grey layer.	Uniform layer in 3 weeks identical in character and amount with that on serum.	In 3 weeks the surface was covered with a very thin grey pellicle which showed no further change. The growth on 2 per cent. glycerin gelatine was identical in appearance excepting that the pellicle was dotted with opaque white foci.	At the end of the 1st week there was a slight initial grey growth, but no further progress until the 3rd week. At the end of the 4th week there was a grey layer not quite uniform. In 5 weeks it was rather thicker and greyish white in parts, due to small confluent colonies. At the end of 2 months delicate grey colonies had appeared in the thinner patches.	Minute grey colonies were visible in the 3rd week. There had been no change 11 weeks later.

Cultures were also isolated from G. P.'s 1016 and 1017, both inoculated with original material. The cultures were identical with Virus VII. direct, but a rather better growth was obtained with G.P. 1017 on potato.

Virus B. VIII.
Mesenteric Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	15th	A moderately thick layer in 3 weeks.	There was a uniform growth a little less than on serum in the 1st week. In the 3rd week the growth became whiter and raised in parts, but on the whole less than on serum. In 6 weeks numerous small raised colonies appeared on the surface.	Inoculated from a serum tube on to a flask of 2 per cent. glycerin broth. In 14 days there was thin grey translucent pellicle speckled with whitish foci, covering about $\frac{1}{3}$ of the surface. In 4 weeks the surface was covered with a greyish translucent membrane studded with raised opaque white colonies.	In 7 days there was a thin uniform grey ground-glass layer, which increased in thickness slightly until the 3rd week. In the 4th, 5th and 6th weeks there was no change. At the end of 10 weeks the surface was studded with minute whitish colonies.	In 14 days there was a greyish layer composed of minute colonies. In the 4th week it was a little thicker and greyish-white, with no subsequent increase.

A culture isolated from Dog 102, fed with culture of original material, showed no alteration.

Virus B. IX.
Mediastinal Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct.	14th.	Thin uniform grey layer not increasing after the 2nd week.	At the end of 7 days there was a grey layer with white points decidedly better than on serum alone. During the 2nd and 3rd weeks the growth became thicker and the colonies whiter and more raised. At the end of the 4th week there was a greyish-white moist layer, at least twice as thick as on serum alone.	On an asparagin medium the surface was covered with a thin grey membrane with a few whitish points. On 5 per cent. glycerin broth in 14 days the surface was partly covered with fairly thick opaque white islands, which sank a few days later.	There was a slight increase at the end of the 1st week. In the 2nd week there was a uniform grey ground-glass layer. Increase took place until the end of the 6th week, when there was a moderately thick grey granular layer, thicker and whiter in places.	At the end of the 4th week there was a thin greyish white layer on the surface of the potato. This increased very little subsequently.

Strains of this virus have been isolated from 15 different animals, including the chimpanzee, monkey, baboon, dog, cat, pig, goat, mongoose, hedgehog, rabbit and guinea-pig; with one exception, that of Dog 50, these have reproduced the characters of the original virus, the pellicle formed on the surface of broth, though varying in thickness, exhibiting the same marked tendency to sink.

VIRUS B. IX.—*continued.*

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Dog 50 through G.P.1708	3rd	Thick uniform greyish-white layer.	In the 1st week the growth was thicker than on serum. At the end of the 2nd week the layer was thick, creamy and markedly wrinkled. Subsequently the wrinkling became coarser and the colour more yellow.	At the end of 6 weeks there was a thick opaque pellicle, creamy in colour, with a finely granular surface. No tendency to sink.	Growth took place from the outset and in 6 weeks the surface was covered by a thick opaque, yellow, coarsely wrinkled layer.	At the end of the 1st week there was a greyish-white layer. This increased until at the end of 6 weeks there was a thick raised yellow growth with a granular surface.

A culture was also isolated from Dog 50 through G.P. 1707; its cultural characters were identical with those of G.P. 1708.

VIRUS B. X.

MESENTERIC GLAND.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
G.P.1070 (Inoculated with original material)	20th Broth 16th	Moderately thick grey layer with a few small whitish colonies.	At the end of the 1st week there was a layer rather thicker than on serum alone. It increased in thickness until the end of the 4th week when there was a greyish white finely wrinkled layer about twice as thick as on serum without glycerin.	In 14 days the surface was incompletely covered by several uniform grey translucent islands. There was slight thickening subsequently, the pellicle remaining translucent. In 4 weeks the growth had sunk.	In 7 days there was a grey translucent layer covered with small white colonies. The growth increased in thickness until the 4th week, becoming greyish white and opaque in patches with fine wrinkling on the under surface.	In 6 weeks numerous minute white colonies were observed. There was considerable increase until the 10th week when the colonies in part coalesced to form a patch of grey growth, and others became raised and slightly yellow.

A culture was isolated from the supramammary gland through G.P. 1072 and was identical in cultural characters.

VIRUS B. XI.

MEDIASTINAL GLAND.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Rabbit 66 (Inoculated with original material)	11th	In 3 weeks there was a thick uniform grey layer.	At the end of the 1st week there was a greyish white layer with small colonies, thicker than on serum alone. During the 2nd and 3rd weeks the growth became thicker and more raised and in 4 weeks there was a layer covered with greyish white colonies at least twice as thick as on serum alone.	In 14 days the surface was nearly covered by several grey translucent islands. In 28 days the surface was completely covered with a greyish translucent pellicle covered with white raised foci. There was very little further thickening but the growth showed no tendency to sink.	In 7 days there was a grey translucent layer with whitish opaque foci. This increased until the 3rd week when there was a greyish white ground-glass layer with small white colonies.	A thin whitish layer was formed in 3 weeks not increasing subsequently.

A culture was also isolated from Rabbit 65 and yielded similar results.

Virus B. XII.

Lung and Mediastinal Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct (Lung)	16th	Uniform layer of moderate thickness with raised white colonies on the surface.	No growth occurred until the end of the 3rd week when minute colonies could be seen with a lens. During the 4th week numerous small grey colonies became visible. At the end of the 6th week there were numerous flat grey colonies mainly discrete and several raised warty colonies of various sizes.	At the end of 6 weeks there were numerous small grey transparent islands which showed no subsequent change.	No growth had occurred at the end of the 9th week.	In 5 weeks there were a few minute whitish raised colonies. In 10 weeks there were fairly numerous raised whitish colonies less than a pin-head in size with grey filmy margins.
Rabbit 98 (Inoculated with the Mediastinal Gland)	17th	Uniform grey layer of moderate thickness.	Growth took place from the outset in the form of a uniform grey layer which progressed at the same rate as on serum alone. At the end of 4 weeks the growths were identical in character and amount.	On an asparagin medium the surface was covered in 5 weeks by a thin grey pellicle speckled with whitish foci.	A very thin grey layer was formed during the 1st week. Slow but definite progress was made and at the end of the 4th week there was a thin translucent layer with a finely granular surface.	Very numerous minute grey colonies were visible in the 4th week.

A culture was also isolated from G.P. 1159 inoculated with original material; this culture yielded similar results to that isolated direct, with the exception that on glycerin agar a few grey colonies appeared during the 9th week.

Virus B. XIII.

Mediastinal Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Rabbit 116 (Inoculated with the original material)	11th	Thin uniform layer.	There was no growth during the first 2 weeks. At the end of the 3rd week there were fairly numerous discrete whitish colonies. At the end of the 4th week the colonies had increased in size, the largest being about the size of a pin head. Around each colony there was a delicate grey marginal expansion which increased until the 6th week, the colonies however remaining discrete.	At the end of 6 weeks there were several delicate grey speckled islands. The surface eventually became covered with a thin semi-transparent pellicle, partly uniform and partly reticulated.	At the end of the 4th week very numerous minute delicate grey colonies could be seen with a hand-lens. In 6 weeks these had increased in size with raised opaque centres and had coalesced in parts.	At the end of the 9th week there was no growth visible. After 3 months fairly numerous minute grey colonies were seen on the centre of the potato.
G.P.1269 (Inoculated with the original material)	13th	Similar.	Colonies were not visible until the 4th week. They had fused together at the end of 6 weeks, forming a thin grey layer.	In 2 months the surface was almost covered by a fine lace-like pellicle which did not increase subsequently.	No growth until the 9th week when two small white raised colonies were visible.	There was no growth until the 9th week, when two small whitish raised colonies were seen. In 3 months these had become conical and faintly yellow. At the end of 4 months the colonies were warty and numerous minute grey ones had appeared.

Virus B. XIV.

Pleura.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct. ('Grapy' masses from Pleura)	13th.	Uniform growth of moderate thickness at the end of the 3rd week.	At the end of the 1st week the growth was a little thicker than on serum alone. After the 3rd week the growths were about equal in amount, but that on glycerin serum was moister, and the surface was roughened by small, raised, white colonies. At the end of the 5th week the growth was thicker than on serum, and the colonies had become yellowish in colour.	On an asparagin medium the surface was covered in 5 weeks with a very delicate grey pellicle, composed of numerous small islands, which, later, sank to the bottom.	Growth during the 1st week was in the form of a thin, grey layer with small, white nodular colonies. During the next 7 weeks steady increase took place, the colonies becoming more raised. At the end of the 9th week there was a fairly thick, greyish-white growth of unequal thickness, covered with small raised colonies. No tendency towards wrinkling.	Numerous minute grey colonies appeared during the 2nd week. During the 3rd week a few became whiter and slightly raised. At the end of the 5th week there was a grey layer, consisting of very small raised colonies. There was no subsequent change.

A culture, isolated from G.P. 1271, inoculated with original material, covered the surface of broth (5 per cent. glycerin) in five weeks with a thin, uniform, translucent grey pellicle, which showed no tendency to sink. On the solid media the culture resembled that obtained direct.

Virus B. XV.

Mesenteric Gland and Mediastinal Gland.

Strain.	Generation	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct. (Mesenteric Gland)	7th. Agar 16th.	Moderately thick grey layer, showing a few white colonies on the surface in the 3rd week.	No growth occurred until the 4th week, when a few scattered grey colonies appeared. At the end of the 6th week the colonies had developed grey filmy margins, coalescing near the condensation water where the colonies were most numerous.	In 6 weeks the surface was covered with loosely aggregated delicate grey islands, speckled with whitish points. Later, the growth all sank. A growth similar in character was obtained on a 2 per cent. glycerin asparagin medium.	There was no growth until the end of the 4th week, when numerous minute grey colonies could be seen. At the end of the 5th week these had coalesced and their centres had become raised and opaque.	Minute greyish-white colonies were just visible at the end of the 5th week. In 7 weeks they were so numerous as to form a greyish-white layer. In 12 weeks a few colonies had become slightly raised; beyond this there was no increase.
G.P. 1348 (Inoculated with the Mediastinal Gland)	5th, Broth 8th.	Similar.	A few scattered minute colonies were seen at the end of the 3rd week. In the 4th week the colonies were small and greyish-white with grey margins.	On a 2 per cent. asparagin medium in 4 weeks, over half the surface was covered with an almost invisible grey network, most of which, at the end of 6 weeks, had sunk to the bottom.	No growth obtained.	In 5 weeks there was one small raised colony. In 7 weeks these were slightly raised, with spreading margins, and numerous very minute grey ones had appeared. In 3 months there were 4 pinhead-sized colonies with grey filmy margins, and numerous smaller colonies over the surface.

A culture was also isolated from G.P. 1347, inoculated with the original material at the same time as G.P. 1348 and showed identical characters.

VIRUS B. XVI.

BRONCHIAL AND MEDIASTINAL GLANDS.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct. (Bronchial Gland)	10th.	Uniform grey layer of moderate thickness.	Numerous minute grey colonies were visible in the 3rd week. These increased slightly in size up to the 4th week, growth then ceasing.	Inoculated on to 5 per cent. glycerin broth from a serum tube. About one third of the surface was covered with delicate grey islands in a month. One of these islands increased, forming at the end of 3 months a greyish white lace-like pellicle 1½ inches in diameter. On a 5 per cent. glycerin gelatine bottle sown at the same time an almost invisible grey film covered the surface in 11 weeks.	No obvious growth in 11 weeks.	There were minute greyish-white colonies visible at the end of the 3rd week. In 5 weeks these were fairly numerous. Similar colonies and numerous minute grey ones could be seen with a hand-lens. There was further increase until the 9th week; the final growth being a thin grey layer surrounding greyish-white raised colonies.
	12th.	Similar.	At the end of the 1st week there was a thin grey layer equal to that on serum. The layer showed no subsequent thickening but numerous discrete grey colonies appeared in the 2nd week, becoming raised and greyish-white in the 6th.	The surface was covered in 15 days partly with a very thin grey layer and partly with small grey islands. In 4 weeks the growth had sunk to the bottom.	At the end of the 1st week there was a thin grey layer with greyish-white points. The points developed into greyish-white colonies, the initial layer showing very little increase.	No trial.
G.P.1399 (Inoculated from the Mediastinal Gland)	3rd.	Uniform grey layer of moderate thickness.	In one week there was a very thin grey layer increasing until the 3rd week, becoming thicker in parts than on serum. In a second pair of tubes the final growth was rather better than on serum alone.		In 7 days there was a thin translucent grey layer which became a little thicker along the margins in 14 days. At the end of 6 weeks numerous delicate grey colonies had developed, some of which had become slightly raised.	At the end of 4th week there were numerous minute greyish-white colonies. In six weeks they had become more numerous. There was very slight increase in size up to the 3rd month.

Virus B. XVII.

Mediastinal Gland and Lung.

Strain.	Generation.	Serum.	Glycerin Serum	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct (Mediastinal Gland)	8th.	Thin uniform grey layer.	There was no change until the 3rd week when the surface was covered with minute discrete grey colonies. These increased a little in size but remained discrete.	The pellicle from the surface of the condensation water of a serum tube was sown on to 5 per cent. glycerin broth and a 2 per cent. glycerine asparagin medium. No growth occurred on the former: the surface of the latter was covered in 8 weeks with a delicate grey transparent membrane with fine white curved lines.	At the end of 3 months there was practically no growth.	A few minute grey points were seen with a lens at the end of the 3rd week. In 3 months there was no change.
G.P.1411 (Inoculated with the Lung)	3rd	Thin uniform grey layer.	There was a uniform layer equal to that on serum at the end of the 1st week. The growths were practically identical at the end of 6 weeks.	The condensation water pellicle sown on a 5 per cent. glycerin broth produced no growth.	No growth was obtained.	Minute grey points were visible with a hand-lens in 7 weeks. In 9 weeks these had formed definite raised colonies with grey filmy margins.

Virus B. XVIII.

Bronchial Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct.	3rd. Agar 11th. Broth 10th.	Uniform layer of moderate thickness.	Numerous minute grey colonies were visible in the 4th week. Subsequently the colonies developed delicate grey filmy margins which had coalesced at the end of the 6th week.	At the end of the 6th week there was one small grey speckled island. Four weeks later there were two small grey islands speckled with opaque white foci.	There was no growth during the first three weeks. At the end of the 6th week there was a thin grey granular patch of growth formed by coalescing colonies some of which had become raised and whitish.	No growth occurred until the 8th week when two minute colonies appeared. At the end of the 12th week there were three slightly raised creamy colonies and several minute grey ones. In 16 weeks there were fairly numerous discrete colonies ranging from a point to a pinhead in size.
Rabbit 160. (Inoculated with the original material)	5th.	Thin grey glazed layer.	Numerous minute colonies appeared in the 3rd week. These extended superficially and in 6 weeks had coalesced to a large extent forming a thin incomplete layer.		No growth.	In the 5th week a patch of minute grey colonies appeared. In the 7th week one was raised and creamy and in 10 weeks the small colonies had become confluent.

Virus B. XIX.
Bronchial Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	5th. Agar 14th.	Uniform grey layer of moderate thickness with whitish colonies on the surface.	No growth occurred during the first 2 weeks. At the end of the 3rd week the surface was covered with very numerous minute grey colonies coalescing to form almost a complete layer at the end of the 4th week. In 6 weeks there was a complete layer studded with greyish white raised colonies. The amount of growth then appeared greater than on serum alone.	A few small grey islands formed on the surface in 3 weeks.	No growth was obtained until the 4th week, when the surface became covered with very numerous minute grey colonies. In the 5th week these had increased in size but remained exceedingly thin and delicate.	In 4 weeks numerous minute white colonies were visible over the surface. In 6 weeks a few became slightly raised. There was no subsequent change.
G.P.1470 (Inoculated with the original material)	6th.	Similar.	During the first 3 weeks there was no growth. At the end of 6 weeks there were fairly numerous raised greyish-white discrete colonies ranging in size from a point up to nearly a pinhead.	No growth during the first 3 weeks. At the end of 6 weeks there were several small whitish nodules floating on the surface.	No growth during the first 3 weeks. At the end of 6 weeks there was a thin grey layer composed of delicate confluent colonies.	No growth at the end of 6 weeks.

Virus B. XX.
Bronchial Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct.	8th. Broth 14th.	At the end of 3 weeks there was a uniform growth of moderate thickness with a few raised white foci.	At the end of the 1st week there was a uniform grey layer, equal in thickness to that on serum, but with more raised foci on the surface. In the second week the growths were still equal. At the end of the 4th week the growth was distinctly thicker than on serum and was moist and greyish-white.	In 2 weeks the surface was practically covered with a delicate grey pellicle in part composed of islands, with scattered opaque white foci. At the end of the 3rd week the growth had sunk.	In 7 days there was a thin uniform grey layer increasing in thickness slightly up to the end of the 3rd week with the development of a few raised colonies. At the end of the 6th week there was a greyish-white granular layer with a few opaque white colonies forming a small warty patch.	A few whitish points were visible in 14 days. In 5 weeks there were fairly numerous minute greyish white colonies. In 8 weeks there was an increase in the number of the colonies which remained minute, some being visible only with a hand lens.
G.P. 1471. (Inoculated with original material)	5th	Uniform grey layer.	In 7 days there was a uniform grey layer, thinner than on serum: this increased slowly, parts becoming raised greyish-white moist and ribbed, parts remaining quite thin and transparent.	In 18 days there were three or four small grey translucent islands, which subsequently sank.	In 7 days there was a thin uniform ground-glass layer which had attained a moderate thickness at the end of the 3rd week, showing a slight fine wrinkling on the under surface. There was very little subsequent increase.	In 14 days there was a thin grey layer on the centre of the potato, which at the end of the 4th week became greyish-white and slightly raised. Growth then ceased.

A culture was also isolated from G.P. 1472, inoculated at the same time and with the same material as G.P. 1471 : this culture gave practically identical growths on the solid media, but on broth formed a uniform transparent grey pellicle covering the surface at the end of 6 weeks.

Virus B. XXI.

Bronchial Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	5th	Moderately thick uniform grey layer.	A few very minute colonies were visible in 14 days. At the end of the 3rd week there were numerous grey colonies closely aggregated in places. In 6 weeks there was very little further change	No growth obtained. On a second bottle several small speckled islands were formed.	In 8 weeks the only change was a slight thickening along one side of the slope of the inoculated material.	In 4 weeks minute grey points were seen. In 6 weeks discrete greyish-white colonies scattered over the surface were distinctly visible. In 8 weeks there were very numerous small slightly raised greyish-white colonies with grey filmy margins.

Virus B. XXII.

(?) Mediastinal Gland.

Strain.	Generation.	Serum	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
G.P.1508 (Inoculated with the original material)	4th.	Uniform grey layer of moderate thickness.	In the 1st week the layer was not so uniform and rather less than that on serum alone. In the 2nd and 3rd weeks the surface of the growth became whiter in parts with fine wrinkling the amounts of growth being about equal on the two media.	In 12 days there were a few delicate grey islands on the surface and growth was starting along the serum. In 3 weeks the surface was covered with an almost transparent pellicle.	In 7 days there was a thin transparent layer which increased slightly during the next 3 weeks. In 6 weeks there was a thin grey translucent layer varying slightly in thickness.	A slight increase of the inoculated material was noticed in 6 weeks.
A culture raised through G.P. 1509 showed similar characters, very little growth being obtained on potato, but a slightly thicker pellicle on broth.						
Dog 72	3rd.	Moderately thick grey glazed layer.	In the 1st week the layer was thicker than on serum without glycerin and greyish white. At the end of four weeks there was a thick moist greyish white layer with fine wrinkling.	The surface was covered in 4 weeks with a uniform grey translucent skin with whitish foci. There was no further thickening.	In 14 days there was a moderately thick dry greyish white layer. In 4 weeks the surface of the growth showed a fine raised wrinkling. There was no further thickening but subsequently opaque creamy colonies developed.	At the end of the 1st week there was a thin grey layer. From this after several weeks raised irregular warty colonies grew.

Virus B. XXIII.

Lung.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	5th	Thin uniform grey layer in 3 weeks.	In 7 days there was a uniform grey layer distinctly better than that on serum. In 14 days the growth was still better and in 3 weeks there was a moist greyish white layer of unequal thickness apparently double the amount of that on serum. No further change was noted.	The surface of the broth was covered with a number of semi-transparent grey islands not forming a complete pellicle. With the 8th generation the surface was in 3 weeks incompletely covered by a pellicle so delicate as to be almost invisible.	In 7 days there was a thin uniform grey ground-glass layer which increased a little in thickness until the end of the 3rd week. There was then a grey translucent layer slightly thicker and opaque in parts.	The surface was covered in 7 days with a greyish growth composed of minute colonies. These slowly increased in size, a few at the end of the 4th week becoming slightly raised—one attaining the size of a pin-head. At the end of the 10th week there was a greyish white layer with a granular surface.

A culture was also isolated from G.P. 1,534 inoculated with the bronchial gland ; this culture resembled that obtained direct, but on broth formed a uniform translucent pellicle which covered the whole surface and began to sink at the end of 6 weeks.

Virus B. XXIV.

Lung and Bronchial Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct ('Grapy' growths from Lung.)	4th.	Uniform layer of moderate thickness.	There was no growth visible until the end of the 3rd week when very numerous minute discrete colonies were observed with a hand lens. At the end of the 4th week they formed a thin grey layer. There was no further change.	No complete pellicle was formed, the surface of the broth after 6 weeks showing only a few very small islands. Some transparent, others greyish-white and granular.	During the first 6 weeks there was no growth. At the end of the 10th week there were three flat grey colonies — the largest about 2 mm. with raised opaque centres.	In 4 weeks minute grey colonies were seen with a hand lens and one or two visible to the naked eye. In 5 weeks the surface was covered with very numerous greyish-white colonies forming a thin layer. There was no subsequent change.
G.P. 1548 (Inoculated with the Bronchial Gland.)	4th.	Uniform layer of moderate thickness at the end of the 3rd week.	Numerous minute colonies were just visible at the end of the 3rd week. In 4 weeks the surface was covered with numerous grey colonies which at the end of 6 weeks had grown larger and to a great extent coalesced.	At the end of six weeks there were numerous transparent islands and opaque white fragments of growth: the surface was not covered.	No growth visible in 10 weeks.	In 5 weeks there were a few minute transparent grey colonies with greyish-white centres. These colonies did not increase in size.

Cultures of this virus were raised direct from the lung and bronchial gland and from the bronchial gland through G.P. 1548. The culture isolated from the bronchial gland was identical with those described above.

Virus B. XXV

Pleura.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	9th	Thin uniform, grey layer not increasing after the 2nd week.	In the 1st week there was a uniform grey layer thicker than on serum alone. At the end of the 2nd week the growth was greyish-white and slightly ribbed round the margins. At the end of the 4th week the layer was two or three times as thick as on serum alone, with a greyish-white roughened surface.	In 11 days the surface was covered with a semi-opaque grey pellicle, climbing up the sides of the bottle. It subsequently began to break up and showed a tendency to sink without further thickening.	In 7 days the surface was covered by a grey layer of unequal thickness. At the end of the 2nd week it was quite thick and opaque in streaks and showed a tendency to wrinkle, which became more definite at the end of the 3rd week, after which there was no change.	Growth took place from the outset in the form of a thin grey moist layer. This remained unchanged until the 2nd month, when small colonies appeared which subsequently became large, irregular, and yellow in colour.
G.P.1607 (Inoculated with the original material)	5th	Similar	Similar.	In three weeks the surface was covered by a thin grey translucent pellicle which did not thicken.	In the 1st week there was a thin grey layer with small whitish patches. This increased until the end of the 3rd week, being for the most part translucent but thick and opaque in patches.	Thin grey layer with the formation of raised white colonies at the end of 5 weeks.

Virus B. XXVI.

Bronchial Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	7th	Uniform grey layer of moderate thickness.	No growth occurred until the 3rd week, when the surface was covered with minute grey colonies. These coalesced in the 4th week, forming a thin grey layer which did not increase.	In 8 weeks $\frac{3}{4}$ of surface was covered with delicate grey islands speckled with opaque foci and small warty nodules. At the end of the 13th week there was no change except for some increase of the whitish nodules. There was no tendency to sink.	No growth occurred in 7 weeks. In 10 weeks there were 2 raised irregular colonies, the largest about the size of a pinhead. In the second generation after 5 weeks there were several small delicate grey colonies. These spread slightly, remaining thin, with minute opaque centres.	In the 3rd and 4th weeks a few minute white colonies became visible and showed no further increase. In the 2nd generation no growth occurred until the 5th week, when minute white colonies were visible. These increased, and in 3 months were fairly numerous, in size from a point up to 1 mm., with delicate grey margins.

A culture was also isolated through Rabbit 380, which was inoculated with the Original Material; it was identical in characters with the direct culture.

Virus B. XXVII.

Diaphragm.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	4th	Uniform grey layer of moderate thickness.	At the end of the 1st week there was a greyish white layer thicker than on serum alone. In the 2nd week it was about twice as thick, and showed at the end of 6 weeks little further change.	In 10 days there was a uniform grey pellicle covering $\frac{3}{4}$rds of the surface. In 14 days the surface was completely covered with a greyish white translucent pellicle, with small opaque patches, already showing a tendency to sink. The growth subsequently sank without further thickening.	At the end of the 1st week the surface was covered by an unequal grey layer of moderate thickness in parts. The thicker patches increased, and became slightly ribbed at the end of the 4th week. In the 2nd generation there was formed at the end of the 4th week a greyish-white translucent layer which had slowly increased from the outset.	In the 1st and 2nd weeks there was a thin grey layer which showed no subsequent increase in thickness. At the end of the 11th week there were scattered small raised white colonies growing from the grey layer. In the 2nd generation there was formed in the 1st week a thin grey layer, which increased slightly up to the end of the 3rd week.

Virus B. XXVIII.

Thoracic Gland. (?)

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	4th	Uniform grey layer of moderate thickness at the end of 3 weeks.	A uniform layer was formed in the first week a little thicker than on serum. It became at the end of the 4th week nearly twice as thick as on serum remaining uniform.	In 14 days there was a grey translucent island about one inch square. At the end of 5 weeks there were 4 grey islands covering about one-sixth of the surface. There was no further increase. On a second bottle the result was similar.	At the end of 12 days there was a grey ground glass layer over the surface. This increased until the 4th week, becoming finally wrinkled in parts. There was no subsequent increase.	During the first 2 weeks no growth was evident. At the end of 3 months there was a thin grey layer, with yellowish colonies up to a millet seed.

Virus B. XXIX.

Mediastinal Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	4th	Uniform grey layer of moderate thickness.	Growth took place from the outset and was rather thicker than on serum alone at the end of the 2nd week. At the end of the 4th week there was a grey layer not quite uniform and nearly twice as thick as on serum alone.	In 4 weeks the surface was not quite covered by a grey translucent almost uniform pellicle with minute white foci. This remained unchanged and showed no tendency to sink.	In 14 days there was slight increase where the inoculated material was thickest, and a patch of thin grey growth near the condensation water. Six weeks later there had been very little change.	There was a thin greyish moist layer becoming definite at the end of the 3rd week. There was no further thickening, but at the end of the 6th week there were three small raised white colonies.

Virus B. XXX.

Bronchial Gland.

Strain.	Generation.	Serum.	Glycerin Serum.	Glycerin Broth.	Glycerin Agar.	Glycerinated Potato.
Direct	3rd.	Thin uniform grey layer.	Growth was of the same character as on serum and progressed at the same rate until the end of the 3rd week. Subsequently the layer became a little thicker and moister than on serum and showed raised white foci on the surface.	In 4 weeks the surface was covered with a thin grey translucent pellicle on which are scattered irregular whitish foci.	In 8 days there was a slight increase of the inoculated material. There was a slow increase until the end of the 4th week, a very thin and incomplete grey layer being formed.	No growth.

THE CULTURAL CHARACTERS OF THE TUBERCLE BACILLI OBTAINED FROM MAN.

Dr. L. COBBETT.

THE CULTURAL CHARACTERS OF THE TUBERCLE BACILLI OBTAINED FROM MAN.

During the last three and a half years tubercle bacilli from sixty cases of human tuberculosis have been cultivated, and many strains raised, some direct from the human tissues, some from animals injected from them, and others again after the strain had passed through a greater or smaller number of animals of various kinds.

Over 160 of these strains have been examined as to their mode of growth on various media, both in primary culture, and in secondary cultures extending over a varying period of time. Many of the strains have been in continuous cultivation since their isolation up to the present time, some for over three years. Many, too, have been grown in large quantities for the injection of animals, and this has offered an opportunity of *measuring* the relative amount of growth on different media.

Cultures have been made on all sorts of media including the serum of many different animals, and egg, as well as serum, agar, broth, and potato to which 5 per cent. of glycerin has been added. Other media also have occasionally been used, such as glycerin-serum-agar, glycerin-egg, glycerin-serum-broth, and broth without any glycerin. The effects of long continued cultivation on serum with and without glycerin have been observed.

When working with cultures of bovine origin at Walpole Farm, I observed that those which were then under observation would not grow upon glycerin-serum, or grew less readily upon that medium than upon serum to which no glycerin had been added. On being transferred to Blythwood Farm and commencing to work with bacilli of human origin, I observed that the majority grew far more luxuriantly on media which contained glycerin than upon those which did not, while a minority grew like the bovine bacilli which I had cultivated at Walpole. The former were only slightly virulent for the ox and rabbit, the latter were highly virulent for these animals. Further experience, however, showed that some of those strains which were highly virulent for these animals, grew rather better on glycerin-serum than upon serum which contained no glycerin, but not so luxuriantly as those which were only slightly virulent for these animals.

Referring now only to tubercle bacilli of human origin, it may be said that different strains grow very variously on a given medium. On serum and egg the differences are not marked; they are far greater on media which contain glycerin. Thus on glycerin-serum there may be a thick nodular continuous cream-coloured growth, or a thin scarcely visible grey film formed of separate points; there may be no growth at all, or anything between those extremes. On glycerin-agar there is often no growth, often a colourless grey film of small points, and frequently again there is a more or less continuous nodular or wrinkled growth of raised cream-coloured colonies. Sometimes, when the colonies are few and widely isolated, they grow into large and wrinkled pyramids. The growth on broth is equally varied. There may be a partial and delicate grey film, or a thick layer which covers the surface, climbs the side of the vessel and becomes wrinkled. Some cultures form a thin delicate reticulated membrane resembling lace, others, large thick islands, the surface of which is roughened by innumerable projections. In some the growth remains very limited and forms a small thick isolated island, which after a long period of apparent quiescence may send out a thin film which rapidly covers the surface. Experiment has shown that a high degree of acidity increases the tendency to the formation of a thick limited patch of growth, and it may well be that the rather sudden changes in the character of growth just described are due to the lessening of the acidity below a certain unfavourable point. This kind of change has been observed in the growing strains which have no tendency to form acid.

The growth of a given strain on a given medium is variable, conditions not entirely under our control apparently playing a dominant part. On liquid media an accidental shake may cause the commencing film to sink, and growth to become arrested. To encourage growth on liquid media various devices have been tried. A small piece of cotton wool in the broth, just sufficient to rise to the surface, has been found to afford a convenient resting place for the bacilli. But the plan which usually succeeds best is to pour a little glycerin-broth into a serum tube which is already growing well, and when floating growth has appeared on this to transfer it to a flask containing the liquid medium.

In consequence of the uncertainty of growth of a given strain on a given medium, in spite of all efforts to obtain constant conditions, no conclusions as to cultural characters can be drawn except after repeated observations, only the best growths obtained with a given strain on a given medium being taken as typical.

No systematic observations covering all the strains grown here have been attempted. I therefore do not propose to submit a detailed report of my observations on cultures, but will briefly summarise the conclusions to which I have been led.

(1) Tubercle bacilli from man fall into two groups, which present fairly distinct characters of growth.

(2) These characters are determined by *quantity* and *rate* of growth on certain culture media. The ultimate quantity appears to me the more significant and useful, but others have thought that the rate of growth was the most distinctive.

(3) The differences in the quantity of growth—as shown by the thickness, colour and other appearances of the film—produced by typical strains of the two groups, is not marked on pure serum, and no classification according to the cultural characters on this medium would be possible. It is on media containing *glycerin* that the difference becomes marked.

It is perhaps most marked on glycerin-agar and glycerin-broth, but those media are apt to be uncertain, and growth on them at the best is slow. Glycerin-serum appears to me to be more certain, and on it results are more quickly obtained.

(4) The two cultural groups into which human tubercle bacilli fall may be defined as including—

1. All those strains the growth of which in early cultures is little, if at all, aided by glycerin; and

2. Those which grow much more luxuriantly on media to which glycerin has been added.

(5) A rough but useful method of making preliminary observations on the cultural characters of a given strain is to sow it on serum and glycerin-serum and to compare the two growths after three weeks. If the growth is decidedly better on glycerin-serum than upon pure serum, it will certainly belong to the second group. If it is better or not markedly inferior on pure serum it will belong to the first group. This test will not apply, as will presently be explained, to old cultures, or to those which have become accustomed to glycerin media.

(6) The unavoidable variations in our culture media, and the variations in characters of growth which may depend upon them, and also perhaps on other factors which

are not under our control, are such that the characters of a given strain cannot be determined without repeated cultivation; and in forming our judgment *only the best growths on a given medium should be considered characteristic.*

(7) It has been shown elsewhere that tubercle bacilli from man, classified according to their *virulence* for certain animals, fall into two principal groups. It is otherwise with the groups into which the bacilli fall, when classified according to their cultural characters.

Cultural characters go, to a certain extent, hand in hand with virulence. The extreme members of each cultural group differ greatly from each other, but there are others where the difference is less marked. Thus while comparative virulence does not seem to vary among the members of each group, cultural characters do. It has even been doubted whether it is reasonable to make two cultural groups, and whether after all the various strains do not form a series in which each presents minimal differences from its neighbours. It is true that examination of the cultural characters on glycerin-agar of a large number of different strains showed that they formed a continuous series in which there was no gap sufficient to justify a division into two groups. But this, I believe, was, to a great extent, explained by the fact that the strains were not strictly comparable in that they had been a very different length of time under cultivation. And it is an easily demonstrable fact that tubercle bacilli gradually adapt themselves to our artificial culture media and grow better upon them after continued cultivation than when first isolated from the animal.

Bacilli which grow little or not at all on glycerin media when freshly isolated from the living animal body acquire the power of growing on these media after long-continued cultivation. And those which grow fairly well on it at first may acquire a luxuriance of growth after several generations. The power of growing, or of growing better on glycerin media, is acquired to some extent by cultivation on media such as serum which contain no glycerin, but the adaptation is carried further if the strain is accustomed to glycerin itself, by being grown on media which contain it. In this way strains of bacilli which belonged originally to the first group come to be indistinguishable from members of the second group; that is, they are indistinguishable by their cultural characters alone; their virulence has not altered.

(8) For these reasons a classification of tubercle bacilli according to their cultural characters can only be made by comparing strains which have been the same length of time under artificial cultivation, and always on the same medium. The shorter the period of cultivation probably the better. If primary cultures could always be used for comparison, I believe that strains with intermediate characters of growth would to a large extent disappear, and each group would contract and become more sharply distinct from the other. It is, of course, too much to ask that cultural characters on such media as glycerin-broth-agar or -potato should be determined in primary cultures, but I am of opinion that early cultures should be exclusively used, that comparison should be made between cultures whose total duration of cultivation is approximately the same. If this were done I admit there would still be a considerable difference between the members of each group, but I believe that the two groups would show themselves to be distinct.

(9) It has been said that cultural characters and virulence go to some extent hand in hand. In the modification experiments, whenever alteration of virulence occurred, there was a corresponding alteration of cultural characters. The original cultures of low virulence grew well on glycerin media, and after they had acquired virulence for the calf, etc. they grew very badly on these media. But on the other hand an alteration of cultural characters may take place without any change of virulence, and virulent strains which would not at first grow on glycerin media were found to have lost no virulence after they had adapted themselves to this medium. Moreover, while the virulent strains originally differed greatly in their capacity to grow on glycerin media no corresponding difference of virulence was observed.

It may, however, be said that the two groups into which human tubercle bacilli are divided by their cultural characters are in the main the same two groups into which they are separated by their comparative virulence for the ox.

After one had gained some experiene, one seldom, if ever, was unable to foretell the comparative virulence of a strain from a cursory study of the characters of its early cultures. It was often on these grounds alone that the decision rested whether or no calves should be injected with 10 mg. doses. Only once was this dose injected unnecessarily, and the mistake was afterwards found to have been due to the use of an unsatisfactory batch of glycerin-serum tubes.

The opinions expressed in the above summary are based not only on the impressions gained day by day and from notes taken at the time, but also on the comparative examination of large numbers of typical cultures on all sorts of media which have been preserved. Early impressions could be checked by the gradual growth of experience, and opinion based on cultures grown a year or more earlier could be corrected by comparing the actual cultures with those grown to-day. Each culture tube was marked by the number of generation, and the total duration of cultivation up to the time of sowing that tube could be ascertained by comparing its date with the date of isolation.

An actual comparison of the relative amount of growth on serum with and without glycerin of certain selected strain may be of interest, though the results are much spoilt by variations in the total duration of artificial cultivation among the strains used.

The method was as follows: When serum cultures were sown for the purpose of getting bacilli with which to inject animals, other cultures were sown on tubes of the same serum to which 5 per cent. of glycerin had been added. The tubes used were large ones with a constricted neck, and the amount of surface exposed by the culture medium in each was 7 in. by more than 1 in. Several tubes of each kind were sown, and if any of them grew less well than their fellows they were rejected. Thus only cultures which were considered satisfactory were measured. At the end of three weeks' incubation all the bacilli from each set of cultures were removed and emulsified by rubbing between ground glass plates and suspended in a known volume of salt solution.

The relative quantity of bacilli in the two suspensions was determined by taking samples of each and centrifuging in capillary tubes, known to be of uniform calibre by careful calibration.

The results are given in the following table.

The serum of adult bovine animals has consistently proved to be a better medium for growing tubercle bacilli than the serum of the calf. The addition of glycerin to the latter makes it a far better medium for the cultivation of bacilli belonging to Group II., but the serum of adult bovine animals is not improved to the same extent. It would seem that it already possesses something which calf serum lacks and which to some extent can be replaced by glycerin. As a consequence, adult serum does not bring out the difference caused by the presence or absence of glycerin in so marked a manner as does calf serum. In the experiments now under consideration calf serum was employed except when otherwise stated. With the serum of one particular cow (No. 9), which was used in several of the experiments, the difference between the amount of growth on serum and glycerin-serum was particularly small.

REPORT ON THE CULTIVATION OF TUBERCLE BACILLI AT BLYTHWOOD.

By Mr. H. J. HUTCHENS (Assistant Investigator).

REPORT ON THE CULTIVATION OF TUBERCLE BACILLI AT BLYTHWOOD FARM.

From November, 1903, to June, 1905, by H. J. Hutchens.

The work here reported was undertaken at Blythwood Farm, while acting as assistant to Dr. Cobbett, with the object of determining the cultural characters of tubercle bacilli derived originally from various tuberculous lesions in the human subject.

At the outset, considerable difficulty was encountered in isolating bacilli in pure culture and in propagating them under conditions of artificial cultivation. The methods of isolation and of cultivation and the preparation of the media selected on which to grow the bacilli in vitro are therefore also described.

In a few instances cultures have been raised by sowing the human material on suitable culture media, but in the vast majority of cases the human material was inoculated into experimental animals, and the lesions subsequently developing in the latter were the immediate source of the cultures.

The different human lesions used for experiment are described as viruses; and cultures obtained either from these lesions or from lesions produced by them in experimental animals as strains of bacilli. The animals from which the different strains were immediately derived are stated in every case.

In all, 141 strains of bacilli derived originally from forty-seven different human sources have been isolated and examined.

The Media used for Cultivation and their Preparation.

The media most commonly used were—

α. Blood serum.

β. Blood serum to which a solution of glycerin had been added.

γ. Glycerin agar.

δ. Glycerin broth.

Preparation of the media.

α. *Blood serum.*—Blood for the preparation of serum was obtained from various animals, viz.—

1. Bull, cow and calf.
2. Horse.
3. Pig.
4. Goat.
5. Dog.
6. Cat.
7. Rabbit.
8. Guinea pig.
9. Monkey.

Blood was collected in suitable sterile vessels and the serum drawn off by means of a sterile bulb and cannula, distributed at once in convenient quantities into sterile test tubes, which were then heated gradually in a sloped position to a temperature of about 75°C. in an atmosphere saturated with water vapour until the serum was so firmly set that it no longer quivered when the tubes were tapped on the thumb-nail. As soon as the tubes had cooled they were carefully and completely sealed with paraffin wax. The tubes were finally incubated for three or four days before being used, in case some error of technique had permitted the entrance of contaminating organisms into one or more tubes.

An iridescence was generally observed on the surface of the serum when it had cooled after coagulation. This did not appear to seriously interfere with the growth of the tubercle bacillus provided that other conditions of the medium were satisfactory. Further experience, however, showed that the formation of an iridescent film could be almost, if not entirely, obviated by raising the temperature very gradually to the point of coagulation, and removing the serum from the inspissator immediately it was firmly set, and before the temperature reached an unnecessarily high degree.

β. *Blood serum with the addition of glycerin.*—Blood serum with the addition of 1·25 per cent. and 5 per cent. of glycerin was very largely used in the work under review. This medium was prepared by adding to ordinary serum before coagulation, in the former case 25 per cent. of its volume of a 5 per cent. solution of glycerin in water, and in the latter case 10 per cent. of a 50 per cent. solution of glycerin in water—the glycerin solutions being, of course, previously sterilized. The medium was then coagulated, sealed and incubated as in the case of blood serum.

γ. *Glycerin Broth.*—The perfectly fresh muscles from the calf or adult bovine animal were finely minced, and tap water added in the proportion of one litre to one pound of meat; 0·5 per cent. sodium chloride added, stirred and allowed to stand overnight. Next morning it was boiled, then strained, and subsequently 2 per cent. Witte's peptone added. It was then boiled again, filtered, and 5 per cent. glycerin added, being finally sterilized in the ordinary manner. The reaction of a broth so prepared was found to be neutral or very faintly acid to litmus, and to phenol-phthalein acid, approximately to the extent of 20 c.c. normal acid per litre.

δ. *Glycerin Agar.*—Was prepared by adding 2 per cent. agar to the glycerin broth prepared as above.

It was usual, especially in the latter part of the work, to seal with paraffin wax all tubes, flasks, and bottles, in which media were stored, and also while they were in the incubator after sowing.

The Selection of the Material from which to isolate Bacilli in Pure Culture.

α. *Human.*—Cultures were raised in several instances directly from human material by scraping the tuberculous tissue and sowing tubes with the material so obtained. Mesenteric and cervical glands have proved particularly useful for this purpose.

β. *Bovine.*—The bovine experimental animals at Blythwood were, in the great majority of cases, inoculated subcutaneously in the neck with material of human origin.

Almost invariably a tuberculous lymphatic gland has been used and generally the prescapular, prepectoral or long posterior mediastinal. Organs such as the lung, liver, spleen and kidney of the bovine, though not often used, have not given good results. Experience early showed that old calcareous and fibrous lesions were also to be avoided, because of the frequency with which cultures sown with such material failed.

γ. *Guinea Pig.*—Any structure affected with the disease was found to readily yield a culture. As a rule a caseous and softened gland, *e.g.* the inguinal, post manubrial, omental or hepatic, or the omentum or spleen or—when the inoculation was intra-peritoneal—a scraping from the peritoneum or the lung have been used. The kidney and liver have not yielded such good results on the relatively few occasions on which they have been utilised.

δ. *Rabbit.*—The omentum, lung, or rib-marrow. Most of the rabbits were inoculated intraperitoneally.

ε. *Monkey.*—A softened and caseous lymphatic gland has been the tissue from which cultures have been sown.

ξ. *Goat.*—The prescapular or long posterior mediastinal gland or the kidney.

η. *Rat.*—Lung and spleen have been used.

When the animal was but slightly affected it was found advisable, in order to prevent disappointment, to sow tubes from several different organs or tissues. This was also done when the lesions present were old and calcareous. Similarly, if only one gland in the bovine or goat was affected better results were obtained by sowing from different parts than all from the same part.

The Technique of raising Primary Cultures.

Various procedures have been adopted for sowing the culture media. Thus, in the case of a softened caseous gland the capsule was sterilised by heat, a small opening made and the pultaceous matter squeezed out drop by drop and smeared over the surface of the medium with a platinum loop.

When the peritoneum was selected, the surface was scraped with a blunt knife and the material so obtained rubbed over the surface of the culture medium.

The omentum was dealt with in a variety of ways; thus, a small piece was sometimes cut off, placed on the surface of the culture medium, and then rubbed over its surface; or, after cutting off a small piece, the fluid and small pieces of tissue obtained by crushing between ground glass plates were rubbed over the medium; or again, if caseous and softened points were present, these were cut into and the material picked out on the point of the knife and used for sowing the tubes.

From the spleen or lung or tuberculous gland which had not softened, it was usual to cut out a small piece, or scrape the tissue with a knife and then sow the tubes, or, having cut out a piece, to crush it between ground glass plates and distribute the crushed tissue with a platinum wire or, if fluid, to pick it up with a piece of glass tubing drawn out to a capillary diameter and spray it over the medium.

After well distributing the material over the surface of the medium the tube was incubated without further interference until growth appeared.

The Development of Primary Cultures.

It has very rarely happened that no growth of tubercle bacilli has occurred when the animal tissue was sown, by one of the methods described, on to the surface of any good serum whatever.

A. *Media used for raising Primary Cultures.*

Coagulated blood serum obtained from various animals with and without the addition of glycerin have been the media commonly used for the purpose of raising primary cultures. Three or four tubes of coagulated blood serum were always used and generally one or two tubes of glycerin serum were sown at the same time. Occasionally a tube of glucose serum or serum agar has also been used. Other media have not been regularly employed for raising primary cultures in these investigations.

B. *Comparison of Values of different Media for Primary Cultures.*

Of the various media used, serum has been the most useful medium upon which to sow primary cultures, for while all tubercle bacilli from whatever source obtained grew more or less readily on serum, bacilli were met with which did not grow at all, or only with great difficulty in primary culture on glycerin serum.

In those cases in which a tube of serum and a tube of glycerin serum were inoculated with material from the same source it was generally found that growth appeared on the serum before it appeared on the glycerin serum.

Glucose serum appeared to be equal to, and perhaps rather better than, serum. And of the various kinds of serum which have been used the most successful results have been obtained with serum from the dog and pig; nevertheless the majority of my cultures have been raised in the first instance on bovine serum, and in my experience a rich golden serum from a milking Jersey cow is as good as any serum obtained.

Glycerin agar has not in my experience proved suitable for raising primary cultures. Serum agar, moreover, has only rarely been satisfactory.

C. *Characters of Growth in Primary Culture.*

These were very variable and were found to depend, in part upon the manner in which the material was sown, and in part upon the number of bacilli present which subsequently multiplied. Other factors influencing the characters of growth in primary culture were the media employed and in the case of serum media the quality of the medium.

When a piece of tissue was merely placed on the medium the bacilli multiplied on the tissue itself and the first evidence that multiplication had occurred was a slight rounding off of the minute ridges and projections and a generally somewhat moist and shiny appearance of the surface of the tissue. Later, minute rounded elevations appeared, and these often formed ultimately large heaped-up cream-coloured nodules or large "crusts."

On the other hand when the surface had been merely rubbed over with scrapings from the tuberculous tissue, or with tissue juices obtained by crushing the material between ground glass plates, or softened pultaceous matter had been sown in a thin layer, or an emulsion sprayed over the surface, the resulting growth had all the characters described later as occurring when subcultures were made on the same media; the only difference observed being that, as a rule, the growth in primary culture was scantier and made its appearance later than in subculture, consequently isolated discrete colonies which often attained considerable size were more commonly seen in the former than in the latter.

A difference between the growth on serum and on glycerin serum was often very well brought out in primary cultures. It was this, when the number of colonies was so small that each remained discrete from its neighbours the number developing on the glycerin serum was in comparable tubes (*i.e.*, tubes prepared from the same batch of serum and inoculated with similar material) often much smaller than on serum and the individual colonies much larger and whiter. This, however, in the case of primary cultures, was found to be a rule which has many exceptions.

In the few cases in which glucose serum has been used it has been noticed, on the other hand, that the number of colonies was very much greater and individuals correspondingly smaller than on serum. Hence, it sometimes happened that a thin ground glass layer formed on the glucose serum while on serum the colonies were discrete but fairly large in number and small in size.

The length of time which elapsed after the tissue had been sown and before growth became apparent to the naked eye varied within wide limits. Sometimes as early as the seventh or eighth day after sowing, frequently at the end of 10 days and very rarely after 3 or 4 days some evidence of growth was plainly visible. In a few cases it has been three or four weeks before the growth had progressed sufficiently far to be visible to the naked eye. In the majority of cases, however, growth made its appearance between the end of the first and the end of the second week.

When pieces of tissue had been sown, whether crushed or not, an early growth not infrequently escaped notice when examined with the naked eye until some experience had been gained in examining primary cultures microscopically. If a microscopical examination be made it could generally be determined at a much earlier period than was possible with the naked eye whether or no growth was taking place. Thus, it was quite usual to find on examining a cover glass preparation that considerable multiplication had occurred even after four days, and by making subcultures at this early period growth was frequently much accelerated. The microscopic appearance which was taken as evidence of growth was the presence of bacilli in clumps instead of occurring singly or in pairs or in relatively quite small clumps as they usually do in tissues.

In some cases with any of the media employed, and particularly in the case of horse serum, the appearance of visible growth was delayed until the third and fourth week. Meanwhile the surface of the medium became covered with a scum. As growth became apparent minute circular areas were seen from which the scum had disappeared. In the centre of each of these areas a minute, practically colourless, speck was found to be present; this was a centre of commencing growth which progressed and assumed the ordinary characters of growth on that medium.

Microscopically the bacilli obtained from primary cultures on serum and glycerine serum were very noticeably shorter and more uniformly stained than those in the animal tissues with which the tubes were inoculated.

D. *Contaminations.*

When sowing primary cultures it was found advisable to inoculate several tubes, and these from different organs or glands, in order to minimise the risk of failing to obtaining a culture. As experience was gained in technique the number of contaminated tubes was considerably reduced, but however much care was bestowed in sowing primary cultures from even recently killed animals my

experience showed that sometimes contaminating organisms were occasionally present in the animal tissue: *e.g.*, culture tubes sown with material from the bovine lung have repeatedly grown organisms other than tubercle; on the other hand the lung of the rabbit has proved one of the most satisfactory tissues with which to sow cultures.

Contaminations generally appeared within forty-eight hours, and were, as a rule, sufficiently obvious; if, however, there was some doubt as to the purity of a culture the condition of the fluid at the bottom of the tube will often assist in settling the difficulty; if the fluid be milky the tube is impure.

But while the majority of contaminations were apparent within forty-eight hours, organisms were sometimes present which were as slow or even slower in producing a recognisable growth than tubercle, and in such a case it has happened that the growth had all the appearances of tubercle, the fluid at the bottom of the tube was clear and every indication of contamination was absent. The only certain method therefore of determining whether a culture was pure or not was to examine it microscopically.

When dealing with the original human material contaminating organisms have occasionally been present which were of such a nature as to be unable to grow under the ordinary conditions of tubercle cultivation, and consequently pure cultures of tubercle bacilli were sometimes raised from material which microscopically was very unpromising.

Pure cultures of tubercle bacilli have however occasionally been recovered from contaminated tubes. The ordinary method of obtaining pure culture by the method of dilution not being applicable, the best chance was found to lie in picking off a trace of growth from various parts of the serum, examining under the microscope, and, if no foreign organisms were present, to sow that particular piece on to a serum tube. When the colonies were discrete then of course recovery was more easily effected.

Subcultures.

When subcultures were made merely for the purpose of perpetuating any strain of bacilli, it was found to be desirable that they should be made from serum on to serum and at intervals of a month to six weeks. The importance of making subcultures from serum on to serum lies in the fact that, as these experiments proved, whatever medium was used the bacilli slowly underwent change in their cultural characters, and this change has been found to be least marked, and to occur most gradually, when serum is used. It has often happened that subcultures have been made from cultures which were much older than six weeks, but experience showed that a risk was then incurred that the bacilli might have died, and this especially if the serum upon which they were last sown had been a poor one.

But when the object of making subcultures was to determine the cultural characters of a particular strain then various other media were used, and those relied upon for this purpose have been:—

Serum.
Glycerin serum.
Glycerin agar.
Glycerin broth.

And as the result of my experience I have come to the conclusion that in order to get reliable results with these "differentiating media" it is absolutely necessary that they should be sown from young vigorous cultures, seven to fourteen days old, growing on a good serum, and as soon after isolation from the animal tissues as possible. And the method I came to adopt as the most desirable when attempting to differentiate strains was to sow three or four serum tubes from the primary culture on serum, and from these to inoculate two or three tubes of serum, glycerin serum, and glycerin agar—if only one tube of each was sown it was found that error was very liable to creep in and give a false impression.

General Statement of the Appearance of Growth of Tubercle Bacilli on each of the four Media—Serum, Glycerin Serum, Glycerin Agar, and Glycerin Broth.

Even with the same strain of bacilli results were very variable, and depended, in addition to the readiness or reluctance of the particular strain under investigation to grow on artificial media, upon the age of the culture from which subcultures were made, the quality of the medium upon which the bacillus was growing, and of that upon which it was sown, the amount of material sown, and the length of time it had been under artificial cultivation. Reliable comparisons, therefore, between different strains were only possible when these disturbing factors had, as far as possible, been excluded.

Serum.—When a good serum has been used as the culture medium no difficulty has been experienced in obtaining a growth with any of the strains of bacilli examined; but at the same time differences in the rate of growth and in the degree of luxuriance ultimately attained have been constantly observed. Further, it has been found that those strains which in general grew with the greatest luxuriance and most rapidly on serum were those which grew also most readily and rapidly and with the greatest luxuriance on other media; and conversely, those whose yield on serum was sparse were those which grew sparingly and slowly and often with difficulty on other media. But though this has been found to be true as a general observation, the differences in the growth on serum were not so constant nor so well marked as the differences found to exist in the growth on glycerin serum, glycerin agar and glycerin broth.

When every precaution had been taken to eliminate as far as possible every disturbing factor it was found that while in some cases growth took place relatively somewhat slowly and the surface became covered eventually with a thin, colourless, almost invisible, dull, uniform, ground-glass layer, in other cases multiplication took place distinctly more rapidly, so that within a week the surface of the medium was covered with a thick layer of growth generally more or less pigmented (if the medium were pigmented) with rounded hemispherical elevations projecting from the general surface of the growth. In these cases, after further incubation the layer of growth had thickened considerably, become more pigmented, the elevations had increased in size and number, and the growth had a tendency, often considerable, to extend on to the glass of the tube, and occasionally a certain degree of wrinkling of the layer was noticed.

These were the two extreme types of growth, but were not by any means the only ones obtained. Every possible intermediate type was met with, filling up the gap between those described, that is, between the least luxuriant, and the most luxuriant. And in all cases the differences were differences in degree only.

When the growth from a serum tube, which often sticks very tightly, was washed off or gently lifted off with a platinum spatula it was found that the surface of the serum was dotted with innumerable minute holes representing points where the bacillus in its growth had actually extended into the surface layer of the medium.

Glycerin Serum.—The appearances resulting from growth on this medium were essentially similar to those already described as seen on serum. The differences in the rate of growth and in the degree of luxuriance attained were, however, more marked than on serum, for while no difficulty was experienced in obtaining a growth on serum with any of the strains, some, those, namely, which exhibited the least luxuriance on serum, grew on glycerin serum only with difficulty and after a delay which was often considerable. On the other hand, those bacilli which grew the most readily and most luxuriantly on serum produced in the same space of time a growth which was in every respect equal to that obtained on serum, and in some cases, especially when the serum was not of the best, the growth on glycerin serum excelled that on serum.

In many cases the growth on glycerin serum was slower in making its appearance than on serum, and in practically every case the growth is whiter on the former than on the latter (when a pigmented serum was used). The layer of growth, too, was frequently more wrinkled in the case of the more luxuriantly growing bacilli when grown on glycerin serum than when grown on serum without the addition of glycerin.

On removing the layer of growth the surface of the medium was frequently seen to be pitted as in the case of serum.

On Glycerin Agar.—In some cases no growth at all has occurred for some weeks, and when the maximum has been finally attained it is very scanty. In such cases the surface did not become uniformly covered, but growth consisted merely of isolated colonies often very few in number, sometimes large, sometimes small, but in either case generally

surrounded by a spreading, often delicately wrinkled, almost colourless halo. These colonies often became considerably heaped up, ridged on the surface and hollowed at the base. If left for three or four months the growth occasionally took a rosette form.

Some strains developed after some delay a very thin, almost colourless layer of growth which, at first uniform, later became irregularly and sparsely studded with small cream-coloured hemispherical nodules.

With other strains again growth commenced without delay, progressed rapidly, and the ultimate yield was considerable, consisting of a thick cream-coloured generally wrinkled layer which was thickly studded with projections from the general surface, these projections resembling "miniature mountain ranges." Moreover, these strains of bacilli had a great tendency to grow beyond the surface of the agar on to the glass sides of the tube.

Intermediate appearances of almost infinite variety have been obtained on this medium.

On Glycerin Broth.—Various methods have been adopted for sowing broth cultures. In most cases the film on the fluid at the bottom of a serum tube has been lifted off with a many-looped platinum wire and floated on to broth. The best results were obtained by transferring this film as soon as it had formed, and in some cases, in order to increase its extent before transferring to broth, a few drops of broth have been added to the fluid already in the serum tube, and the culture replaced in the incubator for a week or so.

In a few cases the film so transferred has at once begun to extend, and has covered the surface of a 6-oz. bottle, laid on its broader face, in two or three weeks or even earlier. But in a majority of cases no extension, or at most a very slight extension, of the film has occurred for some time, perhaps three or four weeks. During this period the pellicle, if the bacilli were alive, thickened and developed very small, white, scattered hemispherical points, and sometimes downgrowths into the depths of the fluid took place. But in these cases once the film had started to extend its area growth over the surface of the liquid medium was generally very rapid, so that the surface was covered not infrequently in so short a space of time as fourteen days. In some cases it has been three or even four months after transferring the film before any increase in area has been observed. It has, however, been frequently noticed that growth ceased before the whole surface was covered, and this has been the case with all strains, whatever their origin.

The resulting pellicle was in some cases very thin and delicate, practically colourless, flat, uniform, and readily broken up into small islands, with but small tendency to climb the sides of the bottle and floating with difficulty.

In other cases the film was somewhat thicker, greyish-white in colour, and generally reticulated.

With many strains of bacilli the pellicle was relatively thick, cream-coloured and opaque, floating much more readily than the thinner films, often thrown into delicate folds and showing a great tendency to climb the sides of the bottles, sometimes to such an extent that the roof was half occupied by the extension of the film. In such cultures small white nodular projections were often seen.

Downgrowths from the under surface of the original material sown occurred indiscriminately, whatever the nature of the resulting pellicle. These stalactites were particularly well marked when there had been much delay before growth began to extend laterally.

The growth on broth has been found to be very capricious, and with the same strain broth has given more variable results than any of the other media described.

Comparison of Values of each of these Media for Comparative Purposes.

While the various strains of tubercle bacilli investigated grew on serum with varying degrees of luxuriance, the medium was found to be of relatively small value for comparative purposes on account of the slight differences which have been found to exist between the most luxuriantly growing strains and those which grow most scantily.

But the differences observed between the various strains on glycerin serum, glycerin agar, and glycerin broth, have been in each case much more marked than on serum.

Comparison of Growths on Serum and on Glycerin Serum.

In these comparisons the same batch of serum has been used in the whole serum and in the glycerin serum tubes.

In comparing the growths produced by the various strains on these two media, it has been found that when a strain was such as to grow only poorly on serum, then its growth on glycerin serum would also be scanty, and in some cases did not occur at all in early sub-culture, and on the other hand, a bacillus which grew luxuriantly on serum grew luxuriantly also on glycerin serum. It has further been observed that in the case of the more luxuriantly growing bacilli, when a poor sample of serum was used, the growth on glycerin serum exceeded in amount the growth on serum, making it appear as though glycerin acted as a substitute for, or supplemented, certain nutritive substances which are absent from or deficient in a poor serum.

With the best samples of serum this difference in the relative amounts of growth of serum and glycerin serum did not occur.

Differentiation of Strains and Viruses.

The characters of growth of tubercle bacilli on serum, glycerin serum, glycerin agar, and glycerin broth have already been considered. Very great difficulty has been experienced in obtaining constant results as regards these characters, but by multiplying, repeating, and controlling the experiments, and by taking every possible care to eliminate as far as possible any disturbance due to factors under control, it has been found that well-marked differences exist between the various strains of different viruses and in a few cases between the different strains of the same viruses.

Some strains of bacilli when sown in primary culture have grown readily on both serum and glycerin serum, and in a relatively short space of time have produced abundant growths on both these media. And in some cases it has been noticed that the amount of growth ultimately resulting on the glycerin serum medium is even more luxuriant than that on the serum medium. Such strains in sub-culture have grown easily, readily, and luxuriantly on serum, glycerin serum, glycerin agar, and glycerin broth. That is to say, that when sown on these media from an early and young subculture growth commenced early, proceeded rapidly, attained its maximum soon and was finally very copious.

Other strains grew well on serum and on glycerin serum both in primary and in subculture, but not quite so rapidly nor so luxuriantly as those already described; and, further, it has been found that these strains when subcultured on to glycerin agar and glycerin broth only commenced to grow after some delay, and it has not infrequently happened that growth was only obtainable on these two last-named media when the strain had been in culture for some weeks, and had passed through several subcultures on serum or glycerin serum. Even when growth was finally obtained, it did not attain the luxuriance of those strains above described.

In the case of some other bacilli, growth has very rarely indeed been obtained on glycerin serum in primary culture, and then traces only, and that after a long period of delay. Such bacilli have been found to grow far better on serum than on any of the other three media under consideration. But even on serum the growth was relatively slow and continued for a long time, while the amount ultimately obtained was small. On glycerin serum it frequently happened that no growth was obtained in the first two or three sub-cultures, and even when it did occur was scanty and very slow in appearing. On glycerin agar it was very rarely indeed that the smallest trace of growth was obtained until these strains had been in culture for some months, and even then it was generally many weeks at the earliest after sowing on the medium before indications of multiplication were visible, and, further, with these bacilli, growth was, as a rule, limited to one or two hemispherical colonies, or a few very small colourless points of growth. On glycerin broth growth was as difficult to obtain as on glycerin agar. When first isolated from the living tissues, bacilli of this character have in my experience consistently failed to grow on glycerin broth, and it was only after repeated sub-culture on serum that a film was ultimately obtained, and even then the film was very thin and delicate.

My experiments have shown that after long-continued cultivation outside the body the growth characters undergo a slow but quite definite change. The longer a strain of bacilli has been kept in artificial culture the more readily and luxuriantly has it grown, and strains which when first isolated were difficult to grow, and on certain media did not grow at all, became so changed as to grow comparatively easily and well on any of the media mentioned.

Conclusions.

From the examination of a very large number of strains of tubercle bacilli derived from many human sources which is summarised in the foregoing report, the following results have been obtained;—

1. In staining properties and microscopic appearances no essential differences have been found in culture between the various strains examined.
2. In cultural characters the only differences which were made out were differences in amount of growth and in time of growth. In all other respects all the strains examined agreed in their cultural characters.
3. The relative capacity of the several strains to grow in artificial culture when first isolated from the tissues of the body varied within limits, for while some grew relatively slowly and scantily, and on some media with great reluctance, others there were which grew more rapidly, more luxuriantly, and with greater readiness, and others, again, with even greater relative rapidity, luxuriance, and ease.
4. The relative capacity to grow outside the body was, however, not constant, for, on the one hand, when any strain of bacilli was kept in artificial culture for some time it was relatively more eugonic than it was at first, and this was equally true of all strains, whatever their initial gonic power. It has also been noticed that bacilli after passage through a rabbit or a goat are slightly more eugonic than after passage through a bovine animal or a guinea-pig. And, on the other hand, in three cases a eugonic bacillus after passage through a series of bovine animals has been converted into a dysgonic bacillus, and cultures obtained from intermediate animals of the passage series was less eugonic than the former and more eugonic than the latter. It has also been found possible to alter gonic power by altering the character of the culture medium. All strains of bacilli grew more rapidly, luxuriantly, and easily on a rich than on a poor serum, and on one that was moist than on one which was dry. Again, for instance, in the case of broth cultures, concentration, dilution, or addition of acid all changed the relative eugony or dysgony of any strain of bacilli.
5. The cultural characters of many of the strains which I have recorded in this report corresponded in every respect to the German "Typus humanus"; others, again, were identical in every detail with their so-called "Typus bovinus." Filling up the gap between the typical typus humanus and the typical typus bovinus a large number of strains of bacilli have come under my observation, which exhibit characters intermediate between the two.

Table showing the different viruses arranged according to the source of the human material and the number of strains of each virus examined.

Heifer 249 (prepectoral gland) - - - - - -	16.viii.04.

Characters of growth in Primary Culture.

On serum.—The number of colonies developing was generally small and individuals remained discrete. They were nearly colourless, minute and hardly raised above the surface.

On glycerin serum.—Rarely any growth and then only after a long lapse of time, and the yield ultimately very poor.

H 10. B.S.—*contd.*

Characters of growth in Sub-culture.

Serum.	Glycerin Serum.	Glycerin Agar.	Glycerin Broth.
Scanty, thin, colourless, and relatively slow-growing.	Very poor, growth much delayed and often not obtained in early sub-cultures. Multiplication much slower than on serum.	Cultures only obtained after being in artificial culture some time. Very slow-growing and ultimate yield scanty.	Not obtained until after being in culture some time. Film very thin, uniform and colourless. * See footnote.

The cultures obtained from the goat grew rather more easily and somewhat more copiously than the other cultures.

* Bacilli obtained from Heifer 231 after being in artificial culture for 15 months covered the surface of glycerin broth contained in a Winchester quart and laid on its side in 14 days.

REPORT ON THE CHANGES IN REACTION PRODUCED IN BROTH BY HUMAN AND BOVINE TUBERCLE BACILLI.

Dr. A. STANLEY GRIFFITH.

ON THE CHANGES IN REACTION PRODUCED IN GLYCERIN BROTH BY HUMAN AND BOVINE TUBERCLE BACILLI.

INTRODUCTION.

In a paper published in 1903* Theobald Smith described a simple method of distinguishing the bovine from the human type of bacilli in broth cultures.

He found that if bovine bacilli are grown on the surface of 3 to 5 per cent. glycerin broth, the acidity of which to begin with is about 2 per cent. the broth becomes steadily less and less acid until finally, when the membrane is complete, an acidity or an alkalinity of about 0·1 to 0·2 per cent. is reached; with human bacilli on the other hand the acidity during the formation of the membrane diminishes at first, falling sometimes as low as 0·3 per cent., then, as the membrane enlarges and thickens, gradually rises again and may reach 2 per cent., but more commonly fluctuates between 0·5 and 1·5 per cent.

Smith claimed that the differences thus brought out established a difference in physiological properties.

This conclusion was based upon the results of the investigation of six strains of tubercle bacilli of human origin and six strains of tubercle bacilli of bovine type; four of the latter were obtained from the bovine, one from a horse and one from a cat; one of the strains of human origin was virulent for calves and rabbits.

Subsequently† three more cultures isolated from the human being were tested after this method; these cultures were found to pursue one of two courses; they either attained a greater than the initial acidity at the end of two to three months, after having first become less acid, or else (as occurred with Human XIII.) the reaction remained after some preliminary fluctuation at an intermediate level of acidity.

Bacilli having the character of human bacilli were found therefore to differ among themselves in the degree of acid production; this phenomenon was constant for the same culture.

In a more recent publication‡ the results of experiments with varying amounts of glycerin are given. With bovine tubercle bacilli the percentage of glycerin had no influence on the final reaction. With slightly virulent human bacilli (except Human XIII.) glycerin up to $\frac{3}{10}$ per cent. did not interfere with a final slightly alkaline reaction, but in broth containing 1 to 2 per cent. the reaction remained slightly acid; in broth containing 3 to 5 per cent. a considerable amount of acid accumulated after several months.

With the human culture mentioned above which produced only a moderate amount of acid, all the broths containing up to 1 per cent. became alkaline; the flask containing 2 per cent. approached and nearly attained the neutral level, but the 3 per cent. broth remained acid.

From these experiments Theobold Smith concluded that in order to bring out the differences at least 3 per cent. glycerin should be employed.

As the method, described in Theobald Smith's first communication on this subject, appeared to supply a valuable means of distinguishing bovine from human tubercle bacilli whenever isolated in pure culture, I was directed by the Commission to repeat Smith's experiments with the different strains of tubercle bacilli which we had isolated from the ox and the human being in order to ascertain whether the same differentiation into two types could be made.

The work in connection with the investigation has been carried out at the Royalcot Laboratory.

Technique.

The cultures have all been grown in half litre flasks, each containing 200 c.c. of broth.

The broth was prepared from beef in the usual way, and in most of the earlier tests was previously fermented for two days with bacillus coli before adding the peptone, salt and glycerin. The initial acidity of the broth has varied from 10 to 21. Glycerin in the majority of cases was added in the proportion of 2 per cent.; in a few cases flasks containing 2 per cent. and 5 per cent. glycerin have been inoculated at the same time. In all cases chemically pure glycerin has been used.

The samples of broth to be tested were withdrawn from the flasks either by means of a syphon fitted into the neck, or by means of a side tube issuing from the bottom of the flask; the flasks with syphons were put in the incubator in an inclined position on a wooden stand. The glass tube forming the syphon passed to the bottom of the broth through a solid rubber cork in which there was also a short length of glass tubing, plugged with wool, which acted as an air inlet.

Over the external extremity of the syphon tube, as well as over that of the side tube, a short length of semi-pressure tubing was placed. In the distal end of the rubber tube a short glass cannula was inserted; the latter passed through a rubber cork fitted into a small test tube; the rubber tubing was clamped with a spring clamp.

Before withdrawing the test sample sufficient broth was withdrawn to empty the syphon or side tube. After removing the sample the small glass cannula was dipped in 2 per cent. lysol to prevent organisms which might have settled thereon, when exposed to the air, from growing in the broth left behind in the tube external to the clamp.

The flasks with side tubes possess several advantages over those with syphons; they occupy less space in the incubator and are easier to inoculate; there is, besides, no disturbance of the pellicle as is sometimes the case with the syphon, which necessarily passes through the centre of the pellicle.

The method of titration was similar to that usually employed for determining the acidity of broth; 2 c.c. of the broth were diluted to 50 or 60 c.c. with distilled water, and after the addition of 0·5 c.c. of a 0·5 per cent. solution of phenol-phthalein in 50 per cent. alcohol, brought to ebullition; an $\frac{N}{10}$ solution of NaOH was then run in until the liquid had assumed a faint but definite pink colour throughout. In every instance two, and often three or more, separate estimations were made and the average taken.

An attempt was at first made to estimate the amount of growth by a gravimetric method; the broth was filtered through a weighed filter paper and the growth collected: the filter was dried in the incubator for three days and then weighed. This method was found to give unreliable results and was abandoned for the volumetric method; this was carried out in the following way; the growth was collected in a graduated test tube and, after finely subdividing the bacillary masses (with a glass rod), centrifugalised for a definite period; then the level of the column of bacilli was immediately read off.

Material Used.

The material for inoculating the flasks has in most cases been taken from broth cultures raised directly from serum; in a few cases the bacillus has grown for some generations on broth before transference to the flasks, in others the pellicle which forms on the surface of the condensation water in a serum tube has been used.

I wish here to acknowledge my great indebtedness to Dr. Eastwood for allowing me the use of his broth cultures, and for having had in many cases broth cultures specially raised for me; in this way the labour of the investigation has been considerably lessened, and I have had the advantage of always using young vigorous cultures.

DISCUSSION AND INTERPRETATION OF EXPERIMENTS.

The Characteristic Reactions of Bovine and Human Cultures.

The results of the experiments are exhibited in tabular form. Considering first the results obtained with the bovine tubercle bacillus, an inspection of the table shows that all the strains have caused a diminution in the acidity of the broth. In four instances the broth became neutral or nearly neutral to phenol-phthalein. In the others the final reaction varied from +5 to +11·5. The total reduction in acidity, *i.e.*, the difference between the initial and the final reaction has varied from 1·5 to 12·5, None of the broths which began with an initial acidity of about + 20 became neutral to phenol-phthalein, the final reaction in these cases never attaining a lower level than +8·5. In several cases the final reaction of the broth was higher than the lowest recorded reaction ; this return to a higher acidity was in no instance great and did not exceed + 2·5.

The virulent strains of human origin have with one exception also caused a diminution in the acidity of the broth. The greatest diminution occurred in the case of H. 28 "C.L." which yielded the least amount of growth. None of the cultures brought the reaction of the broth to the phenol-phthalein neutral point, the final reaction varying between +1·5 and +13·7 ; in some of the strains the diminution in the acidity was very slight. As in the case of bovine strains the final reaction was on several occasions slightly higher than the lowest recorded reaction.

The exception mentioned above occurred in the case of H.19 "S.W." This strain grew slowly but finally yielded an abundant growth ; the final acidity of the broth was +4·5 degrees higher than the initial.

All the slightly virulent strains first caused a diminution in the acidity of the broth (this diminution was not observed in every case on account of the first tests not being made soon enough) and then an increase, the final acidity in the majority of the cases being higher than the initial. This excess of the final over the initial acidity varied from +0·5 to +17. In four instances the final acidity was slightly less than, and in one the same as the initial acidity.

Reactions with Viruses Exhibiting Experimental Variations.

In several instances both with human and bovine viruses strains of tubercle bacilli have been isolated from experimental animals which have differed in cultural characters and pathogenic effects from the first cultures of the virus isolated ; and in one case where the virus consisted of mixed sputum two different kinds of bacilli have been isolated from animals infected with the original material.

The results with these strains I shall consider separately ; they show that the differences in cultural luxuriance are accompanied by a corresponding difference in reaction.

In the case of H.16 J.H. the slightly virulent culture isolated from Calf 273 on two occasions caused the final acidity of the broth to be higher than the initial. The two virulent strains of this virus which have been tested both reduced the acidity of the broth ; the strain from Calf 559 grew better than that from Bull 423A., and it is interesting to note that the diminution in acidity was not so great.

In the case of H.17 Sp. B., the slightly virulent culture isolated from Calf 265 caused once an increase and once a slight diminution in the final acidity of the broth ; another slightly virulent strain (Calf 339) caused a slight increase in the acidity of the broth. Three virulent strains of this virus have been tested : the cultures from Calf 571 and Calf 555 steadily diminished the acidity of the medium ; the latter grown on an unfermented broth (reaction +17·5) caused a greater diminution in acidity than the former grown on a fermented broth (reaction +10) ; in this case (Calf 555) the diluted broth in the cold became quite pink on the addition of phenol-phthalein. The strain from Rabbit 181 was tested four times, twice on fermented broth and twice on unfermented ; on the fermented broth the final reaction was on both occasions slightly less than the initial ; on the unfermented the final acidity was higher than the intial ; it may be mentioned that the culture used for the fermented broth was of an earlier generation than those used for the unfermented and moreover did not grow quite so abundantly.

Four strains of H.2. Sp. A. have been tested ; one, a slightly virulent culture isolated from Calf 111, rendered the broth on two occasions more acid ; the other three, all virulent cultures, caused a slight reduction in acidity.

In the case of H. 13 "A. D." only one culture, that from Calf 301, has been investigated ; this produced an acid reaction in the broth ; two attempts have been made to grow the culture obtained from Rat 15, but without success ; attention may here be drawn to the luxuriant growth obtained with this strain on glucose broth

In two instances the bovine tubercle bacillus has apparently been transformed by passage through the body of a dog into a bacillus having the cultural characters of a Group II. organism

The culture isolated from Dog 18, Virus B. IV. produced a moderately thick pellicle, but unfortunately before the test was completed the broth became contaminated.

The culture isolated from Dog 50, Virus B. IX. produced an acid reaction in the broth.

Reactions obtained under Conditions not strictly Comparable.

The results of certain tests are not included in the tables because of the exceptional conditions under which they were obtained.

These experiments will be described in detail.

Virus B.I. (Guinea-pig 14) was sown on a flask containing a syphon ; at the end of 133 days very little growth had taken place, so the syphon, being required for another flask, was removed and replaced by a solid rubber cork. After five weeks further incubation, active multiplication suddenly set in, and in a very short time the whole surface of the broth was covered. The final reaction of the broth was 4 per litre more acid than the initial reaction [*See* page 63.]

Four strains of human origin, three slightly virulent and one virulent for calves and rabbits, were grown on a fermented broth which took several days to filter ; when at last filtered clear, the broth was considerably diminished in bulk, and the loss was made up with distilled water before adding the peptone, salt and glycerin.

The broth was evidently unfavourable for the full development of the cultures, and the pellicle formed in each case was thin, grey and translucent, and of about the thickness of ordinary tissue paper ; the acidity of the broth was also in each case steadily reduced and in about equal degrees.

The results are important as showing that when slightly virulent tubercle bacilli produce thin membranes, they do not react differently from virulent strains.

Interpretation of Results.

Reviewing the experiments as a whole it is found that all the strains of tubercle bacilli used in the investigation whether of human or bovine origin, first casused a diminution in the acidity of the broth.

In a few cases this diminution steadily progressed until the broth became neutral, or nearly neutral, to phenol-phthalein.

In other cases after a preliminary diminution in acidity, varying in amount, but never great enough to cause the medium to become neutral to phenol-phthalein, the original acidity of the medium was restored and in many cases surpassed.

Besides these cultures, there are others which have produced all intermediate varieties of reaction ; some have steadily reduced the acidity of the broth to a varying extent, but not to the phenol-phthalein neutral point, others after first diminishing the acidity have shown all degrees of return from the lowest point reached to the initial acidity of the broth. If these results are arranged in numerical order, beginning with the strain which has reduced the acidity to the greatest extent and ending with the strain which has produced the greatest amount of acid, it will be found they form a continuous series in which there is no gap indicating that two wholly distinct kinds of bacilli are being dealt with.

Examined with reference to the virulence of the organisms such a series will show that, although there is no sharp line of demarcation, if a line be drawn at a point where the initial and final reaction are the same, all the strains above the line with few exceptions possess high virulence, whilst all the strains below the line with one exception have only slight virulence for the calf and rabbit.

As will be seen from the descriptions of the characters of the pellicles the great majority of the strains which caused a marked diminution in the acidity of the medium

produced much less bulky membranes than those which increased the acidity of the medium.

Virulent tubercle bacilli, as is well-known, grow with more difficulty and ordinarily produce on broth much thinner pellicles than the slightly virulent human bacillus.

The slightly virulent strains on the other hand grow sometimes rapidly, sometimes slowly, but always on a favourable medium finally produce an opaque, wrinkled, or warty membrane often of considerable density.

In the latter cases the amount of growth was obviously greater than that produced by the majority of the bovine bacilli. It was for this reason that an estimate of the amount of growth was made in order to ascertain whether there was any correspondence between it and the change in reaction.

These estimations (volumetric only) together with the corresponding change in reaction are given in tabular form. The table shows that, although the change in reaction is not strictly in accordance with the amount of growth, generally when the growth has been scanty the medium has become less acid, and when the growth has been abundant more acid.

It has been observed in these experiments, and it has also been pointed out by Theobald Smith, that in the case of the slightly virulent bacillus acid accumulates very rapidly towards the end of the experiment. In several instances it has happened that after more than two months' growth the acidity of the medium has been only about equal to, or even less than, the initial acidity, but when tested after the lapse of a few more weeks there was found to have been a sudden rise in the acidity, although no further increase in the thickness of the pellicle could be definitely said to have taken place.

The rise of acidity does not appear to be throughout the experiment in exact proportion to the amount of growth.

It is clear, therefore, that in estimating the relationship between cultural luxuriance and change in reaction another factor, *i.e.*, duration of growth, besides total amount of growth, must be taken into consideration. The growth of the bovine tubercle bacillus stops much sooner than that of the human bacillus; yet both at first react in the same way and if, as has occurred in three cases, the human bacillus ceases to grow when the pellicle formed is still thin and translucent, the change in reaction is not different from that produced by a virulent bacillus growing at the same rate.

Moreover, when virulent strains grow well and produce moderately thick pellicles the diminution in acidity is not so great as when thin membranes are formed. Were it true that all virulent strains caused an alkaline change only in the broth, those virulent strains which have produced moderately good growths ought to have reduced the acidity of the broth to a far greater extent than those which grew scantily. My results clearly show that this greater effect has not followed, and none of the bacilli of Group I. possessed of high virulence, which have grown well have made the broth neutral to phenolphthalein.

In fact, in many instances, the diminution in acidity has been only a very slight one and in one instance when the growth was specially abundant the final reaction was 4 per litre more acid than the initial.

It seems to me that these experiments at any rate prove conclusively that there are strains of tubercle bacilli possessed of high virulence, which have the power, equally with the slightly virulent bacillus, of producing acid out of glycerin. As regards the virulent strains which have reduced the acidity of the medium to a marked degree it would be impossible to say, from information obtained solely by the method of titration, whether acid was or was not produced during the growth of the bacillus; this could only be determined by exact chemical analysis. My own opinion is that in these cases also, except perhaps when the growth was extremely thin, a certain amount of acid, varying with the amount of growth, was formed, which was masked by a much greater production of alkali. This view is based upon the fact brought out by my experiments that the diminution in acidity is less pronounced when the growth is moderate in amount than when it is very scanty.

Summary and Conclusion.

The investigation has shown that when virulent tubercle bacilli, whether of human or bovine origin, are grown on the surface of glycerin broth the acidity of the medium is gradually diminished, the final acidity being less than the initial; the diminution is variable in amount and has in general been greatest when the growth was scantiest.

On the other hand when slightly virulent tubercle bacilli are grown on the surface of glycerin broth the acidity of the medium is at first diminished; then as the pellicle increases in thickness the acidity gradually rises again, the final acidity being higher than the initial. To this general rule exceptions have occurred—for example, the final acidity with bacilli of Group I. has on one occasion exceeded the initial, whilst that in the case of bacilli of Group II. has sometimes been less than the initial—and the distinction which otherwise might have been drawn between the virulent and slightly virulent viruses, the former reducing, the latter increasing the acidity of the medium, is thereby abolished. Yet if no exceptions had occurred it would be incorrect to assert that the distinction so drawn signified a difference in physiological properties; since we cannot neglect variations in reaction attributable merely to differences in amount of growth.

Although the change in reaction has not in every case been in strict accordance with the amount of growth, some correspondence between the two can be noted.

When an organism grows luxuriantly the final acidity of the broth is usually higher than the initial; when an organism grows scantily the reduction in acidity is more pronounced than when the growth is moderate in amount.

My observations therefore clearly show that glycerin broth does not differentiate tubercle bacilli into two classes, and yield no evidence that there is an essential difference in the action of different strains of tubercle bacilli on glycerin.

Comparison with Theobald Smith's Results.

I am able to confirm Theobald Smith in his general statements that the slightly virulent tubercle bacillus of human origin, when grown upon the surface of glycerin broth, first causes a diminution in the acidity of the medium and then an increase, and that there are strains of tubercle bacilli of bovine origin which steadily diminish the acidity of the broth.

My results do not, however, support the conclusion he draws from his experiments—that the differences he has observed point to a difference in physiological properties.

This conclusion is based upon the investigation of a relatively small number of strains, six human and six bovine; yet if the results as set out in his table be analysed and arranged numerically in a series according to the differences in each case between the initial and final reaction, they form, as Dr. Eastwood has pointed out, an unbroken series in which there is nowhere a gap that would justify the conclusion that two essentially different kinds of organisms were dealt with.

In Theobald Smith's paper no mention is made of the amount or character of the final growth, so that it is not possible to institute exact comparisons between his experiments and mine; the only data given are in the case of a virulent organism, Human XI., which always grew scantily and on three occasions failed completely to cover the surface. It is the experience of most observers that virulent tubercle bacilli grow less readily and generally produce a smaller volume of growth than slightly virulent bacilli.

When two related organisms, such as the colon bacillus and the hog cholera bacillus, growing equally rapidly and vigorously, produce in a liquid medium containing a certain sugar, one an acid reaction, the other an alkaline one, differences in biochemical action may be said to have been demonstrated, but it would be incorrect to assert on similar grounds that physiological differences exist between two strains of tubercle bacilli when one produces a feeble membrane which covers only a part of the surface, while the other produces a membrane of considerable density.

In his most recent paper Theobald Smith recommends that in order to bring out the difference between the two kinds of organisms at least 3 per cent. glycerin should be employed; he found that, whereas the percentage of glycerin (traces up to 5 per cent.) had no influence on the final reaction in the case of the bovine bacillus, in the case of the human bacillus acid was only produced in marked degree when 3 to 5 per cent. glycerin was present.

In my experiments with bacilli of low virulence the final acidity has rarely been lower than the initial and this in spite of the fact that the broth I have used has contained 2 per cent. glycerin only. It is indeed noteworthy that the amount of acid produced by the slightly virulent organisms on 2 per cent. glycerin has in general been very much greater than in Theobald Smith's experiments in which 3 to 5 per cent. glycerin was used.

TABLE I.

SUMMARY OF RESULTS WITH TUBERCLE BACILLI OF BOVINE ORIGIN.

Virus and Strain.	Initial reaction of broth.	Lowest recorded reaction.	Final reaction.	Difference between final and initial reaction.	Characters of pellicle.
B I. Cow 44	+12·5	0·0	Neutral or faintly alkaline.	−12·5	Thin and translucent.
,, ,,	+20	+10·	+11·	− 9·	Thin greyish white and lacelike.
B II. Calf 134	+21·	+10·6	+10·6	−10·4	Partly opaque and white, partly thin and filmy.
,, ,,	+21·	+ 8·	+ 8·5	−12·5	Thin grey and almost transparent, with a small warty island.
B IV. Direct	+11·	+2· or 1·	+2· or 1·	−9 or 10·	Thin grey and translucent.
,, ,,	+17·	+11·	+11·	− 6·	Grey translucent membrane of the thickness of ordinary tissue paper.
B V. Goat 2	+21·	+10·	+10·3	− 9·7	Moderately thick opaque white pellicle.
,, ,,	+13·	+ 5·	+ 5·	− 8·	Opaque white pellicle of moderate thickness.
,, ,,	+12·	+ 6·25	+ 7·	− 5·	Opaque whitish islands coverin not more than half the surface.
B V. Heifer 80	+11·	+ 7·	+ 8·5	− 2·5	Thin grey and translucent.
B VIII. Direct	+17·	—	+13·5	− 6·	Thin grey membrane with opaque whitish patches covering about half the surface.
B IX. G.P. 1069	+21·	+10·2	+11·	−10·	Greyish translucent speckled membrane which sank at the end of the fifth week.
B IX. Lemur 2	+17·5	+11·5	+11·5	− 5·5	Partly opaque white and slightly warty, partly thin and translucent; the whole of the pellicle had sunk at the end of the 38th day.
B IX. Dog 60	+17·5	+15·	+16·	− 1·5	Thin membrane which sank at the end of the 4th week.
B X. G.P. 1070	+20·	+13·5	+11·5	− 8·5	Thin and grey and studded with opaque raised colonies.
B XI. Rabbit 66	+21·	+ 8·	+10·5	−10·5	Partly greyish-white semi-opaque, and studded with raised colonies, partly thin and translucent.
B XIII. Rabbit 116	+10·	+ 1·	+ 3·	− 7·	Very thin.
B XIV. Direct	+17·	+11·	+11·	− 6·	Thin grey membrane with opaque warty patches, covering a little more than half the surface.
B XV. Direct	+10·	+ 4·5	+ 7·	− 3·	Resembled ordinary tissue paper.
B XVIII. Direct	+10·	+ 1·	+ 3·	− 7·	Very thin.

TABLE II.

SUMMARY OF RESULTS WITH TUBERCLE BACILLI OF HUMAN ORIGIN.

(*a*) Virulent Strains.

Virus and Strain.	Initial reaction of broth.	Lowest recorded reaction.	Final reaction.	Difference between initial and final reaction.	Characters of pellicle.
H 7. "C.M." Cow 73	+21·	+ 8·3	+ 9·6	−11·4	Thin translucent membrane containing a few opaque patches.
H 7. "C.M." Cow 73	+20·	+ 9·	+13·7	−63·	Thin grey and translucent with thicker white patches.
H 10. "B.S." Heifer 231	+13·	+ 3·75	+ 3·75	− 9·25	Thin grey and translucent with some opaque white patches.
H 14. "F.S." Calf 125	+13·	+ 3·5	+ 5·	− 8·	Opaque warty islands surrounded by a delicate grey membrane.
H 16. "J.H." ,, 559	+13·	+ 4·5	+ 5·25	− 7·75	Broken up into islands, some thin and grey, others thicker and more opaque.
H 16. "J.H." ,, 423a	+13·	+ 3·75	+ 3·75	− 9·25	Thin and filmy, with three opaque islands.
H 19. "S.W." Heifer 239	+17·5	—	+22·	+ 4·5	Resembled heavy lace.
H 28. "C.L." Direct -	+14·	+ 1·5	+ 1·5	−12·5	Almost transparent except for two small opaque patches.
H 29. "M.F." G.P. 1334	+17·5	+14·	+14·	− 3·5	Partly thick yellow and warty; partly greyish-white and translucent.
H 31. "L.F." Direct -	+14·	+ 6·5	+ 6·5	− 7·75	Surface half covered with moderately thick white pellicle; rest with a few delicate grey islands.
H 32. "Y.W." Direct Mesenteric glands.]	+13·	+ 4·5	+ 7·	− 6·	Thin and grey with a few opaque whitish patches.
H 38. "J.M." G.P. 793	+15·	+ 7·	+ 7·	− 8·	Thin grey and translucent.

DETAILED DESCRIPTION OF THE EXPERIMENTS.

VIRUS B I.—(Cow 44.)

The culture used for the inoculation was taken from broth and was the sixth generation, the last three of which had been grown on broth.

The broth was fermented and contained 2 per cent. glycerin.

During the first 70 days the inoculated material showed no increase in area but slowly increased in thickness becoming warty and nodular; then a grey film began to grow from the margins; this gradually extended and the whole surface was covered on the 91st day, the growth climbing up the sides of the flask; the pellicle subsequently thickened a little and became greyish white and slightly wrinkled.

Initial titration - -	-+12·5
Reaction after 77 days -	-+12
(pellicle slowly extending)	
Reaction after 91 days -	-+ 8
(surface covered)	
Reaction after 96 days -	-+ 2 or 3
,, ,, 106 ,, -	-+ 3
,, ,, 151 ,, -	-broth neutral or faintly alkaline.

VIRUS B I.—(Cow 44.)

The above culture was inoculated at the same time on 5 per cent. glycerin broth.

Growth during the first 4 weeks as opaque white nodules with stalactitic down-growths; in the fifth week a grey marginal film developed around the nodules; at the end of the seventh week the whole surface was covered with a pellicle which climbed up the sides of the flask; the growth was grey and showed whitish striae radiating out from a central group of opaque nodules; the pellicle thickened slightly and was finally greyish white and finely wrinkled.

The broth became nearly neutral to phenol-phthalein after the surface was covered; then a development of moulds stopped the experiment.

(This experiment is not included in the table).

VIRUS B I.—(Cow 44.)

The culture used for the inoculation was the twenty-third generation, the last four of which were grown on glycerin broth.

The broth was not fermented and contained 2 per cent. glycerin.

Growth took place from the outset and in a little more than 3 weeks the surface was covered with a thin greyish-white lace-like membrane; during the next fortnight the pellicle became slightly thicker and whiter, some parts being a little thinner than others. The pellicle then broke up into islands and all further growth ceased, many of the islands becoming moist and falling to the bottom of the flask.

Initial reaction - - -	- + 20
Reaction after 21 days -	- + 12
,, ,, 39 ,, -	- + 10
,, ,, 60 ,, -	- + 10·5
,, ,, 79 ,, -	- + 11

VIRUS B I.—(Original Material, through Guinea-Pig 14.)

The culture used was the twenty-second generation, the last two of which were grown on broth.

The broth was fermented and contained 5 per cent. glycerin.

Examined 133 days after inoculation the inoculated material was seen to have increased in thickness and area only to a very slight extent; there was an appearance, however, around the margins as if growth might take place. The syphon apparatus was removed and the flask stoppered with a solid rubber cork. A month later the small island had not apparently undergone any change. Examined 9 days later the whole surface was found covered with a thin grey pellicle traversed by wavy white lines radiating out from an opaque central patch. Subsequently the membrane thickened slightly and became greyish white.

Initial reaction - - -	- + 12
Reaction after 164 days - -	- + 16
,, ,, 191 ,, - -	- + 16

VIRUS B II.—(Calf 134.)

The culture used for the inoculation was taken from broth and was the seventh generation, the first six of which were grown on pure serum.

The broth was fermented and contained 2 per cent. glycerin.

In ten days the inoculated material had doubled in area; in 39 days there was an irregular greyish white pellicle covering an area equal to that of a two-shilling piece; this slowly increased in area and thickness and in 75 days there was an opaque greyish white patch covering not quite two-thirds of the surface with a grey film spreading out from the margins; the grey film continued to extend but the whole surface was not covered until the 121st day; the filmy growth then sank to the bottom leaving the opaque patch floating.

Initial reaction - - - -	- +21
Reaction after 82 days - -	- +11·2
,, ,, 121 ,, - -	- +10·6

VIRUS B II.—(Calf 134.)

A flask of the same broth, but containing 5 per cent. glycerin, was inoculated at the same time as the above from the same culture.

In 29 days there was a whitish opaque island the size of a sixpenny bit; this slowly increased in thickness, becoming warty on the surface and showing short stalactitic processes on the under surface; around the margins were delicate grey thread-like processes; after 81 days there was very little further increase, but the growth was yellower and more curved. On the 110th day the whole surface was found covered with a thin grey almost transparent pellicle traversed by fine wavy whitish threads radiating outwards from the opaque patch, which was now of a brownish yellow colour thick and warty, and with raised edges.

VIRUS B II.—(Bull 22.)

The culture used for the inoculation was taken from glycerin milk and was the 21st generation, nine of which had been grown on glycerin media.

The broth was not fermented and contained 2 per cent. glycerin.

Growth was very slow; ten weeks after inoculation there were three grey translucent islands, the largest about the size of a shilling, each showing one or two small opaque white thickenings.

Initial reaction - - - -	+ 17·5
Reaction after 94 days - - -	+ 15·75

(This experiment is not included in the table.)

VIRUS B IV.—(Original Material.)

The culture used was taken from broth and was the tenth generation, the last two of which were grown on broth.

The broth was fermented and contained 2 per cent. glycerin.

Forty-four days after there was a series of small opaque nodules with stalactitic downgrowths; the nodules slowly increased in size and on the 57th day were seen to be forming grey marginal films; on the 69th day the whole surface was nearly covered with a thin greyish translucent film through which curved whitish lines radiated from the opaque nodules; there was no subsequent increase in the thickness of the film.

Initial reaction - - - -	+ 11
Reaction after 77 days - -	+ 4
(surface nearly covered).	
Reaction after 96 days - - -	+ 3·5
„ „ 106 „ - - -	+ 2 or 1

VIRUS B IV.—(Original Material.)

The culture used was the 41st generation, the last seven of which had been grown on liquid media.

The broth was unfermented and contained 2 per cent. glycerin.

Growth took place from the outset and in 13 days the whole surface of the broth was covered with a thin uniform grey membrane. At the end of five weeks the membrane was grey translucent finely wrinkled and about the thickness of ordinary tissue paper. Subsequently no further increase in thickness of the pellicle was observed.

Initial reaction - - - - -	+ 17
Reaction after 21 days - - -	+ 12·5
„ „ 72 „ - - -	+ 11

VIRUS B IV.—(Calf 118.)

The culture used for the inoculation was taken from glycerin milk and was the 22nd generation, the last eleven of which had been grown on glycerin media.

The broth was not fermented and contained 2 per cent. glycerin.

Sixteen days after inoculation there was a delicate grey island with whitish thickenings slightly larger than a shilling; this slowly increased and ten weeks after inoculation about a quarter of the surface was covered; the pellicle was grey and translucent and showed opaque white thickenings; there was no further increase in the area of the pellicle and the opaque thickenings acquired a chalky white appearance.

Initial reaction - - - -	+ 17·5
Reaction after 94 days - - -	+ 16·5

(This experiment is not included in the tabular summary of results.)

VIRUS B IV.—(Dog 18.)

The culture used was taken from broth and was the eleventh generation.

The broth was unfermented and contained 2 per cent. glycerin.

Three weeks after inoculation there was an opaque white warty island, measuring 3 by 1½ in. On the fiftieth day two-thirds of the surface was covered with a moderately thick opaque white warty pellicle, whilst on the rest of the surface there were floating some opaque nodules with grey filmy margins. Sixteen days later the broth was found to have become turbid. A smear preparation made from the pellicle showed a few large diplococci scattered about.

„ „ 77 „	-	-	-	- + 8·5

VIRUS B V.—(Goat 2.)

The culture used was the seventh generation and was the first broth subculture.

The broth was fermented and contained 2 per cent. glycerin.

In 34 days there was an island the size of a two-shilling piece; in 42 days a third and in 47 days the whole of the surface was covered with a pellicle which subsequently became of a moderate thickness; it was whitish and the surface was moist and reticulated. The initial reaction was + 13 and the final + 5.

VIRUS B V.—(Goat 2.)

The culture used was the tenth generation and was the second broth subculture.

The broth was fermented and contained 2 per cent. glycerin.

In 31 days the whole surface was covered, the growth climbing up the sides of the flask; the pellicle was not uniform, part being opaque white and granular on the surface, the rest thin grey and translucent; later the growth became thicker and more uniform; it was opaque white wrinkled and resembled heavy lace; no increase in thickness was observed after the 64th day; on the 110th day scattered pearly white colonies were seen to have developed on the surface

VIRUS H 17. "Sp. B."—(Calf 339, through Guinea-pig 1235.)

The culture used was the seventeenth generation and was the first broth subculture.

The broth was unfermented and contained 2 per cent. glycerin.

At the end of 40 days about half the surface was covered with an opaque greyish white pellicle with a reticulated surface. Finally the whole surface of the broth became covered with a thick opaque white faintly creamy pellicle with a slightly wrinkled very warty surface.

Initial reaction	+ 18
Reaction after 93 days	+ 20·5

VIRUS H 17. "Sp. B."—(Rabbit 181.)

Culture fourth generation from broth.

The culture was used to inoculate two flasks of fermented broth, one containing 2 per cent., the other 5 per cent. glycerin.

On the 2 per cent. glycerin broth in 24 days there was a number of greyish white islands covering about a quarter of the surface; in 40 days the greater part of the surface was covered with opaque milky white islands; these subsequently, beyond a slight increase in thickness, showed no change and never coalesced.

Initial reaction	+ 13
Reaction after 40 days	+ 12
,, ,, 104 ,,	+ 9·5

On the 5 per cent. glycerin the inoculated material showed a slight increase in thickness and area; in 52 days there was a thick white patch, irregular in outline, covering between one-sixth and one-fifth of the surface, and at the end of 82 days about a third of the surface was covered; examined at the end of 102 days a thin grey film was seen to have grown out from the margins; this slowly expanded, but never completely covered the remaining surface.

VIRUS H 17. "Sp. B."—(Rabbit 181.)

The culture used was the thirteenth generation and was the first broth subculture.

The broth was not fermented and contained 2 per cent. glycerin.

Three weeks after inoculation there was an irregular unequally thick island which covered about a sixth of the surface; the island was for the most part opaque and white, the margins being thin and grey. Growth proceeded very slowly; on the forty-ninth day only about half the surface was covered, and on the eighty-fifth day not more than three-quarters; the whole surface was never completely covered; the pellicle, finally, was moderately thick opaque and stiff and had a wavy or wrinkled surface; the pellicle along the top of the waves, or ridges, was cracked.

VIRUS H 17. "Sp. B."—(Rabbit 181.)

The culture was the nineteenth generation and was the first broth subculture.

The broth was unfermented and contained 2 per cent. glycerin.

Growth from the outset was very slow; eighteen days after inoculation there was an opaque white island the size of a half-crown piece; this gradually extended and finally the whole surface was covered with a thick wrinkled slightly warty pellicle of a whitish colour with a faint yellow tinge.

Initial reaction	+ 20
Reaction after 71 days	+ 21

VIRUS H 17. "Sp. B." (Calf 555.)

The culture used was the twelfth generation and was the first broth subculture.

The broth was not fermented and contained 2 per cent. glycerin.

Fourteen days after inoculation the surface of the broth was completely covered with a thin grey membrane which climbed up the sides of the flask: the pellicle was not uniformly thin but showed slightly opaque greyish white patches. There was very little subsequent increase in the thickness of the pellicle which towards the end of the experiment broke up into islands and formed a small amount of deposit at the bottom of the flask.

Initial reaction	+ 17·5	
Reaction after 14 days	+ 11	
,, ,, 29 ,,	+ 6

,, ,, 94 ,, - -	+ 4·75

VIRUS H 12. "H.N." (Calf 123.)

The culture used was the sixteenth generation and was the first broth subculture.

The broth was unfermented and contained 2 per cent. glycerin.

Growth at first was very slow; at the end of the twenty-fourth day there was an opaque white slightly warty patch, the size of a shilling piece, dark-coloured around the margins and on the under surface. Examined on the fifty-second day the whole surface was found covered with a greyish white semi-opaque finely wrinkled pellicle in the midst of which there was a thick opaque dark-coloured warty patch; the pellicle subsequently became thicker, more wrinkled and creamy white in colour. A few days before the termination of the experiment the broth became slightly cloudy; no contaminating organisms were found in microscopical preparations of the pellicle and subcultures from the broth on serum remained sterile.

Reaction after 104 days -	+ 17·6
,, ,, 124 ,, -	+ 28 broth (acid to litmus.)

VIRUS H 19. "S.W."—(Heifer 239.)

The culture used was the sixteenth generation and was the first broth subculture.

The broth was unfermented and contained 2 per cent. glycerin.

A fortnight after inoculation there was a small opaque island, about the diameter of a sixpenny piece, unequal in thickness and very irregular on the surface. This very slowly increased in area and at the end of three months was about the size of a half-crown piece; it was very thick, opaque and greyish white and had a warty irregular surface. About this time whitish processes began to grow from one margin; these formed a network and when a small patch had formed became detached from the opaque island.

The network expanded very slowly and on the 198th day nearly the whole surface of the broth was covered with a lace-like network composed of moderately thick white trabeculæ; these trabeculæ were very brittle, the slightest jar of the flask causing pieces to break off and sink; eventually the whole surface was covered and the interstices of the network became filled in with an extremely thin grey membrane. In the meantime the original island gradually became moist around the edges and finally sank to the bottom of the fluid.

VIRUS H 49. "T.C."—(Original material.)

The culture used for the inoculation was the tenth generation, and was the first broth subculture.

The broth was not fermented, and contained 2 per cent. glycerin.

Fourteen days after inoculation there were three or four small grey islands with whitish thickenings. On the twenty-eighth day three-quarters of the surface was covered with a somewhat broken-up pellicle, not uniformly thick; the greater part was opaque and greyish-white, but parts were quite thin and translucent.

In five weeks the whole surface was covered, but the growth did not climb up the sides of the flask; the pellicle was broken up, and was wavy and parchment-like; the space between the opaque parts was filled with thin, grey growth. The pellicle showed no further increase in thickness, but opaque raised colonies developed on the surface which attained the diameter of a pin's head

VIRUS H 53. "D.H."—(Original material, through Guinea-Pig 1482.)

The culture used for the inoculation was taken from the surface of glycerin milk and was the twelfth generation.

The broth was not fermented, and contained 2 per cent. glycerin.

A fortnight after the inoculation the whole surface was covered with a thin, translucent, grey pellicle, of about the thickness of tissue paper; it was finely wrinkled, and climbed up the sides of the flask. A month after the inoculation the pellicle was found to have become thicker and whiter in patches, the rest of the membrane remaining thin and translucent. Subsequently there was no further growth, and the pellicle broke up into islands, some of which sank; the experiment was terminated on the 56th day on account of a small mould colony appearing in the depth of the broth.

VIRUS H 54. "C.W."—(Original material, through Guinea-Pig 1609.)

The culture used was the sixth generation and was the first broth subculture.

The broth was not fermented and contained 2 per cent. glycerin.

Growth took place from the outset, but was very slow. At the end of a month about a quarter of the surface was covered with an opaque creamy warty patch. At the end of 6 weeks two-thirds and at the end of 8 weeks practically the whole of the surface was covered. The pellicle was for the most part thick, creamy and warty, but parts, chiefly around the margins, were thinner, greyish white, and more wrinkled.

VIRUS H 55. "R.D."—(Original material—Mesenteric Gland.)

The culture used was the fifth generation and was the first broth subculture.

The broth was not fermented and contained 2 per cent. glycerin.

Seven days after inoculation there was a small grey island speckled with opaque white foci. This slowly expanded, and in three weeks half the surface was covered. At the end of 5 weeks the whole surface was covered, and the growth had begun to climb up the sides of the flask. In the seventh week there was a moderately thick, greyish-white, slightly wrinkled membrane showing minute raised white foci scattered over the surface; at one part there was a small warty patch. There was no subsequent increase in the thickness of the pellicle, but the surface became studded with raised opaque colonies.

ADDITIONAL OBSERVATIONS ON THE CHANGES IN REACTION PRODUCED IN GLYCERIN BROTH BY HUMAN AND BOVINE TUBERCLE BACILLI.

After the experiments detailed above were completed an additional series of experiments was undertaken with the object of controlling the previous results.

Twelve strains of bovine origin and sixteen strains of human origin, of which five were virulent for the calf and rabbit, have been investigated.

In order to have the experimental conditions in this series perfectly uniform throughout, the same batch of broth was used; chemically pure glycerin was added to it in the proportion of 3 per cent.

The broth proved to be an extremely favourable medium, and all the cultures grew with great vigour, some of the virulent strains producing pellicles which were almost equal to, and in many cases apparently greater in thickness than, those produced by some of the slightly virulent strains.

After sowing, the flasks were not disturbed until at least two months had elapsed; samples were then withdrawn and tested. In four instances the growths produced by bovine bacilli had, before the end of six weeks, sunk to the bottom of the fluid.

In each case the final amount of growth was estimated volumetrically.

The results have been tabulated and arranged in a numerical series beginning with the strain which reduced the acidity to the greatest extent, and ending with the ones which produced the greatest amount of acid.

The series clearly shows that different strains of tubercle bacilli cannot be differentiated into two classes by means of this test; as in the first experiments, the differences between the initial and final reactions form an unbroken series, in which there is no gap which would justify such a distinction.

With only six strains of tubercle bacilli was the reaction of the broth finally more acid than at the start; this increase varied from +0·5 to +8; the strains causing this increase in acidity have only slight virulence for the calf and rabbit.

In all the other cases the final acidity was less than the initial, but in no case did the broth become neutral to phenol-phthalein, the difference between the initial and final reactions varying from 1 to 9·5. Five of these strains have been shown to possess only slight virulence for the calf and rabbit, whilst the rest are highly virulent.

It is therefore not even possible to draw a line at the point where the initial and final reactions are the same, and say that all the strains which reduce the acidity in any degree are virulent, and that all the strains which increase the acidity are slightly virulent.

It may next be enquired how far the change in reaction has accorded with the amount of growth.

An inspection of the column which gives the volumetric estimations shows that the amount of growth produced by the three strains which caused the greatest reduction in acidity is much less than that produced by the three which formed the most acid. But with these the correspondence ceases; in fact the remaining estimations seem to show that the majority of the more virulent bacilli are incapable of producing with the same or an even greater bulk of growth as much acid as the less virulent bacilli.*

The questions therefore arise—do these differences indicate an essential difference in biochemical action, or are they differences in degree only?

In the case of the slightly virulent organism, it seems quite clear that two chemical processes are at work in the broth—one a reduction in acidity which predominates at first, the other a production of acid which becomes more and more marked as the experiment continues, and which can be referred to some splitting up of the glycerin.

The action of the virulent tubercle bacillus is not so readily explained; Theobald Smith is of the opinion that bovine tubercle bacilli, although they utilise glycerin, do not form acid out of it, and are capable, therefore, of producing an alkaline change only in the medium. If this be so, the change in the alkaline direction ought to bear some proportion to the amount of growth, and to be greater when the growth is luxuriant than when it is scanty, as it is when there is no glycerin in the broth, or when glucose is substituted for glycerin. On examining the list it will be noticed that the diminution in acidity brought about by the virulent tubercle bacilli is in all cases comparatively a slight one, and is in many cases less with large amounts of growth than it is with small ones.

It is difficult to explain these results except on the hypothesis that the virulent tubercle bacilli act on, and produce acid out of, the glycerin in the same way as, though to a less marked extent than the slightly virulent bacillus.

The more saprophytic bacilli no doubt from the outset attack and decompose the glycerin with the formation of acid more readily and in greater degree than the less saprophytic organisms, and it is for this reason that the initial diminution in acidity is never great with the slightly virulent bacillus.

Although the majority of the virulent strains have reduced the acidity of the broth to a greater extent than the slightly virulent, yet it is possible to select out of the series virulent strains and slightly virulent strains which have yielded identical results (*e.g.*, Virus B. XI., and H. 16 J.H. Calf 273, H. 54 C.W. and H. 38 J.M.) or strains in which the differences are so slight as to be negligible, (*e.g.*, Virus B. XI. and H. 50 P.H.).

The differences observed, therefore, in the action of different strains of tubercle bacilli on glycerin broth are, in my opinion, differences in degree and not in kind, and are attributable to variations in saprophytic power which have been shown to exist on other media.

---

* It must be pointed out, in connection with the amount of growth, that the volumetric estimations have not in all cases given results quite consistent with the naked eye characters of the growth, *e. g.*, Virus B. XIV. described as being thin, grey and translucent yielded a greater volume of growth than H. 52, T.F., which was moderately thick and creamy-white, and other examples could be found.

THE CHANGES IN REACTION PRODUCED IN GLUCOSE BROTH BY HUMAN AND BOVINE TUBERCLE BACILLI.

Eleven strains of tubercle bacilli, two of bovine origin and nine of human origin, have been tested on broth containing 1 to 2 per cent. glucose; two of the strains of human origin were virulent, six were slightly virulent, and one (H 53 "D.H.") had intermediate virulence for bovines.

The method of testing the change in reaction has been the same as that employed for the glycerin broth.

Glucose is a very satisfactory substitute for glycerin; all the cultures have grown well and the pellicles formed have been similar in character to those on glycerin broth; in the case of H. 13 "A.D." Rat 15, a strain which grows with great difficulty on glycerin media, a very luxuriant growth was obtained, almost equal to the best obtained with slightly virulent bacilli.

Four different samples of broth were used, with an initial reaction varying from +7 to +22.

The results of the tests are given in Table VI.

In all cases the acidity of the broth was gradually diminished, the virulent strains reacting in precisely the same way as the slightly virulent; the greatest diminution in acidity occurred with those strains which produced the most luxuriant growths.

These experiments with glucose broth, therefore, do not afford results which would justify the division of tubercle bacilli into two classes.

DETAILED DESCRIPTION OF THE EXPERIMENTS WITH GLUCOSE BROTH.

VIRUS H 11. "E.D."—(Calf 221, through Guinea-Pig 918.)

The culture used for the inoculation was the twelfth generation, and was the first broth subculture.

The broth was fermented, and contained 1 per cent. glucose.

Sixteen days after inoculation three-fourths of the surface were covered with a pellicle, unequal in thickness and broken up into islands. About a fortnight later the whole surface was covered; the growth was for the most part opaque, creamy yellow, and very warty; the rest was thinner and greyish white. Subsequently no change in the character of the pellicle was noted.

Initial reaction				-	+10
Reaction after	19	days		-	+ 6
,, ,,	32	,,		-	+ 7
,, ,,	70	,,		-	+ 5·5
,, ,,	102	,,		-	+ 5·5

The broth in the cold became deeply pink on the addition of phenol phthalein, the colour being more pronounced than in the case of H 34. C.U.

VIRUS H 2. "Sp. A."—(Calf 83, through Guinea-Pig 618.)

The culture used for the inoculation was the first broth subculture.

The broth was fermented, and contained 1 per cent. glucose.

Growth at first was slow; 18 days after inoculation there was an opaque whitish warty nodule, 5 m.m. in diameter; this fourteen days later measured 1 c.m. in diameter, and was thick, opaque and showed stalactitic processes on the under surface.

The island slowly expanded, and on the forty-fifth day a third of the surface was covered with an opaque, creamy-white patch with a honey-combed surface; around the free margin of this patch delicate grey growth began to form; this spread over the surface to some extent, then broke up into small islands; growth then ceased.

Initial reaction				-	+12
Reaction after	50	days		-	+ 6
,, ,,	91	,,		-	+ 6·5
,, ,,	99	,,		-	+ 6

The broth gave a deep pink colouration with phenol phthalein in the cold.

VIRUS H 17. "Sp. B."—(Calf 265.)

The culture used was the thirteenth generation and was the first broth subculture.

The broth was fermented and contained 2 per cent. glucose.

In 9 days the whole surface was covered with a thin grey membrane traversed by fine wavy lines. The membrane increased rapidly in thickness and climbed up the sides of the flask. Five weeks after inoculation it was moderately thick, opaque, uniform and wrinkled, and creamy white in colour. There was very little subsequent increase in thickness and finally all the growth sank to the bottom of the fluid.

VIRUS H 34 "C.U."—(Original material, through Guinea-Pig 236.)

The culture used was the tenth generation and was the first broth subculture.

The broth was fermented and contained 1 per cent. glucose.

In a fortnight the whole surface of the broth was covered with a uniform thin greyish-white pellicle speckled with opaque, white foci. The pellicle increased to a moderate thickness, and 5 weeks after inoculation was opaque white, or faintly creamy, and slightly wrinkled.

Later the pellicle broke up into islands and some of the growth sank.

The broth before boiling gave a deep pink colour with phenol phthalein.

VIRUS B. V.—(Original material, through Guinea-Pig 711.)

The culture used was the eighth generation, the last two of which had been grown on broth.

The broth was fermented and contained 1·25 per cent. glucose.

Growth took place from the outset, and in 16 days the whole surface was covered with a thin grey membrane, traversed by many fine wavy lines. The membrane became finely wrinkled but increased very little in thickness; the wavy lines, however, grew thicker, whiter, and more opaque.

Initial reaction			-	-	-	- + 7
Reaction after	16	days	-	-	-	- + 6

VIRUS B. XIV.—(Original material, through Guinea-Pig 1271.)

The culture used was the fifth generation and was the first broth subculture.

The broth was fermented and contained 1·25 per cent glucose.

In 3 weeks the whole surface was covered with a thin grey uniform lace-like membrane, dotted over the surface of which were numerous small white foci.

The membrane thickened slightly, and was finally translucent, finely wrinkled, and dotted on the surface with minute whitish foci.

H 43. "F.F."—(Original Material.)

The culture used was the sixth generation and was the first broth subculture.

The broth was fermented, and contained 1·25 per cent. glucose.

Eleven days after inoculation there was a whitish island the size of a two-shilling piece; this gradually extended, and in 8 weeks about three-quarters of the surface was covered. The pellicle was greyish-white and was partly wrinkled, and partly smooth and studded with raised nodules. The pellicle subsequently became thicker and acquired a creamy colour, but the surface was not completely covered; the nodules increased in size, some attaining a diameter of 2 and 3 millimetres.

H 13. "A.D."—(Rat 15.)

The culture used was the sixteenth generation and was the first broth subculture.

The broth was unfermented and contained 2 per cent. glucose.

Twenty days later there was a small patch consisting of raised opaque yellow nodules. The patch increased slowly in area and the nodules became larger; in the meantime on the sixty-first day a grey marginal film began to form; this gradually extended and at last the whole surface was covered. At the end of the experiment more than half of the pellicle was thick wrinkled and creamy, whilst the rest was thin grey and translucent and showed scattered raised foci.

H 53. "D.H." (Original material, through Guinea-Pig 1482).

The culture used was the twelfth generation and was the first broth subculture.

The broth was unfermented and contained 2 per cent. glucose.

Growth was very slow. On the sixty-first day there were three small yellow nodules, one of which was surrounded by a grey film. One hundred and one days after inoculation the whole surface was covered with a grey translucent finely wrinkled membrane showing in the centre a yellow warty patch. The membrane increased in thickness and become more wrinkled, the summits of the wrinkles having a yellowish tinge.

PRELIMINARY NOTE ON THE CHANGES IN REACTION PRODUCED IN GLYCERINATED LITMUS MILK BY HUMAN AND BOVINE TUBERCLE BACILLI.

The method adopted in the foregoing experiments for studying the chemical changes produced in a liquid medium by the tubercle bacillus has the disadvantage that exact information of the variations in reaction is gained only at relatively long intervals.

In order, therefore, to be able to watch the succession of changes in reaction from day to day, milk coloured with litmus was substituted for broth.

Milk was chosen as the basis of the medium, in preference to broth, on account of the readiness with which slight changes in the colour of the litmus can be detected in it. The medium was prepared in the following way: fresh cow's milk was taken and allowed to stand for twenty-four hours, or more, in a cool place to allow the cream to separate; the milk was then syphoned from beneath the cream and coloured with blue litmus solution; after the addition of 2 per cent. glycerin, the fluid was run into six-ounce medicine bottles, about thirty cubic centimetres being placed in each bottle, and fractionally sterilized; at the end of the sterilization the milk was bluish with a faint purplish tinge. After inoculation the bottles were sealed with paraffin.

On this milk medium tubercle bacilli grow very well and form pellicles indistinguishable in character from those produced by the same bacilli on glycerin broth.

The sequence of changes produced in the colour of the medium during the growth of the bacillus is very characteristic. At first as the inoculated material slowly increases in area the milk acquires a deeper blue tint; then, as the pellicle expands and thickens, the original colour of the medium is regained and gradually changed to a bright red; and finally the milk clots.

This type of reaction is exhibited by all the slightly virulent organisms, when luxuriant growths are obtained; occasionally when the growth has failed to cover the surface, or is thinner than usual, the milk has become red, but has remained unclotted.

Virulent tubercle bacilli up to a certain stage bring about exactly the same changes in the colour of the medium; the colour is at first changed into a more intense blue and then gradually to pink or red; none of the virulent tubercle bacilli has, however, clotted the milk, but in the case of H 49 "T.C.," there was towards the end of the experiment a slight deposition of casein.

With some virulent bacilli the deep blue colour produced at the outset has remained permanent; this has occurred when there has been only a slight increase of the inoculated material or when the membrane formed, though complete, has been delicate and transparent.

On many occasions the litmus, after turning pink, has been completely decolourised, the milk becoming perfectly white; when the bottles in which this change has taken place are removed from the incubator and allowed to stand at room temperature, first the pink colour slowly returns and finally the original colour is restored, wholly or partially according to the amount of growth which had been produced on the surface; control bottles of milk placed under the same conditions underwent no change. These phenomena, which appear to depend upon oxygenation, have been observed with slightly virulent bacilli as well as with virulent bacilli, but most frequently with the latter. In no instance when the colour of the milk has been discharged has clotting taken place; the clots so far produced have all been red.

On litmus milk without glycerin in one case a slightly virulent human bacillus grew with moderate luxuriance and the milk became slightly decolourised and acquired a faint pinkish tinge; in all other cases growth has been scanty and the milk has remained very blue.

Further experiments with this medium are being made: *e.g.*, the influence on the reaction of varying percentages of glycerin and of some of the sugars.

The results so far obtained however show that the medium does not differentiate tubercle bacilli into two classes and in this respect they are in agreement with those obtained by the use of glycerin broth.

MODIFICATION EXPERIMENTS WITH TUBERCLE BACILLI OF BOVINE ORIGIN.

Dr. A. STANLEY GRIFFITH and **Dr. F. GRIFFITH.**

MODIFICATION EXPERIMENTS WITH TUBERCLE BACILLI OF BOVINE ORIGIN.

It has been shown that different strains of bovine bacilli vary within limits in their capacity for growth on media containing glycerin, but it has been impossible to demonstrate any corresponding variation in virulence. Experiments have been carried out to ascertain whether these properties, cultural characters and virulence, are stable or capable of being altered artificially on culture media or by animal passage.

MODIFICATION BY CULTURE.

On pure serum tubercle bacilli of bovine origin grow better in later than in early generations. Prolonged cultivation on this medium does not in our opinion alter the characteristic type of reaction towards media containing glycerin. With viruses of Class I. sub-cultivated on serum for over two years and then grown on solid glycerin media there is the same initial delay and formation of discrete colonies, but the colonies produced are more numerous, and the final amount of growth is generally greater; and this is the case with all viruses, that the amount of growth ultimately produced on all varieties of media, glycerinated or otherwise, accords with the general increase in saprophytic power.

By sub-culture on glycerin media all viruses grow with increased luxuriance on solid glycerin media, and after a number of sub-cultures varying with different strains a type of growth is finally produced which is practically the same for all viruses. This is an opaque warty or slightly wrinkled layer distinctly better than that obtained with the most easy growing viruses of Class III. The change is most marked in those strains which grow originally with the greatest difficulty. These cultures which have been modified by repeated subculture on solid media containing glycerin show no corresponding increase in capacity to grow on glycerin broth. On the other hand by repeated transferences from broth to broth a greater vigour of growth on this medium can be established.

The increased capacity to grow on glycerin media is retained by the cultures after their passage through animals (calf, rabbit, and guinea-pig), and is manifested by the readiness with which they grow in primary culture on glycerin serum and glycerinated potato.

The cultures so recovered show no greater luxuriance as a result of their residence in the animal body, and even after successive passages through animals, the cultures intervening being maintained purely on glycerin media, do not grow better than the same cultures modified by residence on glycerin media alone.

The influence of glycerin produces no diminution in the virulence of the bovine bacilli for rabbits and calves. This has been shown by comparing the virulence of cultures which have been kept on glycerin serum for periods up to nine months with that of the same cultures which have been kept on serum alone.

MODIFICATION BY ANIMAL PASSAGE.

CHIMPANZEE PASSAGES.

Two Viruses, B. IV. and B. IX., are being passed through two series of chimpanzees; these viruses were chosen as representatives of classes of bovine bacilli which showed respectively the greatest and the least reluctance to grow on glycerin media.

Passage with Virus B. IV.

The first animal in this series (No. 8) was fed with 107 c.c. of milk of Cow 172 [Table IV. A.] containing 10,000,000 tubercle bacilli and died 144 days later of broncho-pneumonia of pneumo-coccal origin. The tuberculous disease was limited to the intestines and the nearest glands. Cultures were isolated from a colic and a mesenteric gland.

The second animal of the series (No. 10) was fed with 0·1 mg. of the culture derived from the colic gland of Chimpanzee 8; the culture used was in the fifth generation, 21 days old, and had been in cultivation for a total period of 117 days. This chimpanzee died in 113 days and showed general tuberculosis with extensive ulceration of the intestinal mucous membrane and great enlargement and caseation of the mesenteric glands. Cultures were isolated from a mesenteric gland and from the lung through a guinea-pig.

The third animal of the series (No. 16) was fed with 0·01 mg. of the culture derived from the mesenteric gland of Chimpanzee 10; the culture used was 21 days old, the third generation, and had been in cultivation for a total period of 60 days. This animal died in 91 days of general tuberculosis, the mesenteric and retro-peritoneal glands being much enlarged and extensively caseated. Cultures were isolated from the spleen and a portal gland.

A fourth chimpanzee, No. 22, was inoculated subcutaneously with 0·001 mg. of the culture isolated from the spleen and died in 87 days of general tuberculosis.

The cultures derived from each of the first three animals, namely, from the mesenteric and colic glands of Chimpanzee 8, from the mesenteric glands and lung of Chimpanzee 10, and from the spleen of Chimpanzee 16, have been tested on the differential media employed in the classification of the bovine viruses. All the strains showed cultural characters identical with those of the culture obtained from the original material of Virus B. IV., producing for example discrete colonies on glycerin serum after the initial delay characteristic of the viruses in Class I.

Cultures from each of the three Chimpanzees, 8, 10 and 16, have been inoculated into rabbits. The results show that there has been no alteration in virulence. (*See* Table 1, page 94.)

Passage with Virus B. IX.

The first chimpanzee in this series (No. 14) was fed with 1·1 mg. of culture derived from the original material of Virus B. IX.; the culture used was 20 days old, twentieth generation, and had been in cultivation for a total period of 447 days. This animal died in 63 days of general tuberculosis, the intestines and mesenteric glands being

severely affected. Cultures were isolated from a cervical, a mesenteric, and an ileo-colic gland, and there was no change either in cultural characters or virulence for rabbits and guinea-pigs.

The second chimpanzee in the series (No. 18) was fed with 0·01 mg. of the culture derived from the ileo-colic gland of Chimpanzee 14; the culture used was the fourth generation, 22 days old, and had been in cultivation for a total period of 91 days. This culture was primarily raised on glycerin serum, and was grown on glycerin media until the time of its inoculation. The chimpanzee died in 116 days of general tuberculosis, and cultures were isolated from the spleen. The culture shows no change in cultural characters as a result of its passage through the animal body; there is, however, a slightly increased capacity to grow on glycerin media due to its residence on glycerin media before its inoculation. Its virulence for rabbits is unchanged.

Cultures from other Chimpanzees.

Cultures have also been recovered from two other chimpanzees; one, No. 4, inoculated subcutaneously with 1 mg. of culture from the original material of Virus B. IV. died in 56 days of general tuberculosis; the other, No. 6 fed for a week with tuberculous milk (Virus B. IV.) and killed 100 days after the experiment began also showed general tuberculosis. The cultures showed no change in cultural characters or in their virulence for rabbits.

BABOON AND MONKEY PASSAGES.

Six passage experiments are being carried out on monkeys and baboons with three viruses, one with Virus B. IV., two with Virus B. I., and three with Virus B. IX.

Cultures of Virus B. I. recovered from two rhesus monkeys, Nos. 80 and 82, which were killed, when dying of general tuberculosis, in 165 and 176 days respectively, showed no alteration in cultural characters or virulence for rabbits.

Baboon Passage.—Virus B. I.

The first animal (No. 8) was fed with milk of Cow 64 (Table I. A) containing one million tubercle bacilli. It was killed 97 days later and showed general tuberculosis, the infection spreading from the tonsils. A rabbit inoculated intraperitoneally with an emulsion made from a cervical gland died in 88 days of general tuberculosis.

The second baboon (No. 64) was fed with 0·1 mg. of culture, which had been in cultivation 533 days, derived from the cervical gland of Baboon 8. This animal died in 101 days of severe general tuberculosis, and cultures were obtained from the lung and a cervical gland.

The culture isolated from Baboon 8 showed a distinct increase in luxuriance on the differential media, growing almost as well as the bovine viruses in Class III.

The culture obtained from the lung of Baboon 64 showed a further increase in luxuriance, behaving in the same way as a bovine culture which has been modified by repeated sub-cultivation on glycerin media. Its virulence for rabbits, however, is equal to that of any of the bovine viruses.

Baboon Passage.—Virus B. IV.

The first baboon, No. 22, in this series was fed for 30 days with tuberculous milk of Cow 172 (Table IV. A) and died of general tuberculosis 90 days after the experiment began. A culture was isolated from a cervical gland, and after it had been in cultivation for a total period of 292 days, was given by the mouth in a dose of 0·1 mg. to Baboon 62. This baboon died in 136 days of general tuberculosis and cultures were isolated from the spleen and the lung. These strains as well as that from Baboon 22 were identical in every respect with the culture derived from the original material of Virus B. IV., and there was no alteration in virulence as a result of the passage.

It is interesting to note the stability of the cultural characters and virulence of this virus after prolonged cultivation on artificial media and passage through the bodies of chimpanzees and baboons.

Rhesus Monkey. Baboon Passage.—Virus B. I.

A rhesus monkey, No. 76, was fed with 0·01 mg. of culture derived from Cow 44 (Table I. A.) and was killed when dying 228 days later; the post-mortem examination showed general tuberculosis. A culture was isolated from the spleen and this, after it had been in cultivation for a total period of 310 days, was given by the mouth in a dose of 0·1 mg. to Baboon 66, the second animal of the series.

The baboon died in 133 days of general tuberculosis, and cultures were isolated from the spleen and a cervical gland.

The cultures obtained from both animals were unchanged in their characters on artificial media, and in their virulence for rabbits and guinea-pigs.

Rhesus Monkey. Passage.—Virus B. IX.

The first animal of this series (No. 110) fed with 1·0 mg. of culture from the original material of Virus IX., was killed when dying 80 days after inoculation: the post-mortem examination showed general tuberculosis of a severe type. A culture was isolated from an iliac gland and inoculated subcutaneously into two monkeys, No. 114 receiving a dose of 1·0 mg. and No. 116 a dose of 0·01 mg.

Both animals died of acute miliary tuberculosis in 34 and 36 days respectively, and cultures were isolated in each case from an axillary gland.

The culture from Monkey 116 was used to feed Monkeys 130 and 132, the former receiving 0·01 mg., the latter 0·0001 mg. These animals died in 86 and 134 days respectively of general tuberculosis.

The culture isolated from each of the three animals (Nos. 110, 116 and 132) in the passage showed no change in cultural characters or in virulence for rabbits.

Mangabey Monkey and Baboon Passage.

Virus B. IX.

A Mangabey monkey was fed with 1·0 mg. of culture derived from the original material of Virus B. IX.; it died in 80 days of general tuberculosis.

A culture was isolated from a lumbar gland, and after it had been in cultivation for a total period of 49 days was used to feed a mandrill baboon.

This animal, No. 68, received a dose of 0·1 mg. and died in 46 days of cysticercosis (taenia saginata). The only visible sign of tuberculosis was an enlarged and caseous retro-pharyngeal gland; a guinea-pig, however, inoculated with an emulsion of the spleen died of general tuberculosis.

A culture was made from the retro-pharyngeal gland and used to feed Monkeys 126 and 128, the former receiving a dose of 0·01 mg., the latter a dose of 0·0001 mg. Monkey 126 died in 120 days of general tuberculosis; Monkey 128 was killed in 169 days, and showed no tuberculosis.

The cultures isolated from each animal in the series showed no change in cultural characters and that from the last animal (No. 126) was virulent for rabbits.

Lemur Passage.

Virus B. IX.

The first lemur, No. 2, was fed with 1·0 mg. of culture from the original material of Virus B. IX., and when killed after 46 days was found to have general tuberculosis. A culture was isolated from a mesenteric gland and inoculated subcutaneously into Lemurs 12 and 10, the former receiving 1·0 mg., the latter 0·1 mg. Both animals died prematurely in 23 and 30 days respectively. In Lemur 12 there was a local lesion, caseation of the nearest glands and early tuberculosis of the spleen.

In Lemur 10 the disease was rather more advanced, a few minute tubercles being visible in the lungs, spleen and liver. The culture obtained from Lemur 2 was unchanged in cultural characters and virulence for rabbits.

EXPERIMENTS WITH DOGS.

Dogs have been inoculated, subcutaneously, intraperitoneally, and by feeding, with the object of testing their susceptibility towards the bovine bacillus. The experiments have shown that the dog possesses a high degree of resistance. In six instances cultures have been recovered and investigated to ascertain whether residence in this refractory species had produced any modification in cultural characters or virulence. Each case will be considered separately.

Case 1.

Dog 26 was inoculated intraperitoneally with an emulsion containing 10·15 million bacilli, made from the tuberculous organs of Guinea-Pigs 1148 and 1150. (Milk of Cow 172, Virus B. IV.); it was killed when very ill after 71 days and showed general tuberculosis. A culture obtained from a ventral mediastinal gland was identical with that derived from the original material of Virus B. IV.

Case 2.

Dog 72 was inoculated intraperitoneally with 1·0 mg. of culture obtained from a guinea-pig inoculated with the original material of Virus B. XXII., and was killed, in good health, 156 days later.

The post-mortem examination showed a few yellow foci in the liver, numerous tubercles of a doubtful nature in the kidneys, and several small fibrous tubercles and two or three small grey nodules in the lungs. There was no tuberculosis of the peritoneum and no tubercle bacilli were demonstrated in any of the lesions except in one of the grey nodules in the lungs, from which a culture was isolated.

This culture grows distinctly better than the culture inoculated, and is now classed amongst the most easy-growing bovine viruses; its virulence for rabbits, however, is unchanged.

The culture was inoculated subcutaneously into another dog, No. 126, in a dose of 10 mg. This animal was killed 99 days after inoculation and showed an ulcer at the site of inoculation, slight tuberculosis of the inguinal and bronchial glands, numerous tubercles in the liver and three translucent tubercles in the lungs. A culture isolated from the liver is still under investigation.

Case 3.

Dog 18 was fed with an emulsion of guinea-pig organs containing 10·15 million tubercle bacilli (Virus B. IV.) and showed after 135 days tuberculosis of two mesenteric glands and a few doubtful tubercles in the lung.

The culture isolated from a mesenteric gland grows much more luxuriantly than Virus B. IV. direct (for characters, *see* page 8 of Culture Report), and indeed better than any of the more easy growing bovine viruses. The culture is not virulent for rabbits and a young dog fed with 50 mg. and killed after 77 days showed slight tuberculosis of the pharyngeal, mesenteric and bronchial glands and two tubercles in the lungs.

Case 4.

Dog 50 was fed with 1·0 mg. of culture of Virus B. IX. and was killed 111 days after; the post-mortem examination showed no disease of the alimentary tract or glands in connection with it, but there was tuberculosis of one lobe of the lung. Two guinea-pigs were inoculated from the lung and a culture was isolated from each.

Both these strains grew more luxuriantly than the original culture of Virus B. IX. and even better than that obtained from Dog 18, corresponding in characters with the slightly virulent bacilli of human origin. A calf inoculated subcutaneously with 50 mg. of culture and killed after 91 days showed a local lesion, caseation of the nearest glands and a few tubercles in the lungs and some of the lymphatic glands. A second calf inoculated subcutaneously with an emulsion (containing 83·7 million tubercle bacilli) made from the prescapular gland of the first calf showed, when killed after 64 days, a local lesion only. The results in rabbits also demonstrated the slightly virulent nature of the culture.

Two adult dogs were inoculated each with 10 mg., one subcutaneously, the other by feeding to ascertain the degree of virulence of the culture for dogs. The dogs were killed 99 and 98 days after inoculation respectively. The former showed a small healing ulcer at the seat of inoculation and two grey tubercles in the lung; in the latter there was a single tubercle in the lung and no sign of tuberculosis elsewhere.

Case 5.

Dog 60 was fed with the same dose of the same culture as Dog 50. It was killed 112 days after, and showed tuberculosis limited to the pharyngeal, mesenteric, and ileo-colic glands.

The culture recovered from a mesenteric gland showed no definite increase in luxuriance and was virulent for rabbits.

This culture was obtained in the usual way by scraping the whole surface of a primary tube. In addition a number of single colonies from one primary culture have been separately investigated with regard to their virulence for rabbits, one colony having shown on glycerin agar a distinct increase in luxuriance; the rabbits were inoculated subcutaneously, each with the growth from a single glycerin agar tube in the third generation, and all developed general tuberculosis of the usual type.

A dog, No. 84, was fed with 50 mg. of the culture obtained in the ordinary way; when killed 73 days later it showed a few miliary tubercles in the lungs and no disease elsewhere. A culture isolated direct from one of the tubercles possesses the same cultural characters and virulence as that from the original virus.

A young dog, No. 130, was inoculated subcutaneously with 48 mg. of culture derived from the single colony, No. 3, which had shown a slightly increased power of growth; this animal died in 85 days of acute general tuberculosis, the inoculation having been partly intraperitoneal; a culture isolated from the liver is still under investigation.

Case 6.

Dog 102, an adult animal, was fed with 100 mg. of culture derived from the original material of Virus B. VIII.; it was killed in 72 days and showed one nodule in the lung and no disease elsewhere; a culture isolated direct from the nodule resembled that inoculated.

Additional Experiments.

The results in two cases, Dog 18 and Dog 50, namely, the isolation of cultures entirely different from those inoculated, suggested the possibility that the bovine bacillus could be modified in cultural characters and virulence by residence in the body of the dog. In order to exclude natural tuberculosis as a source of error the method of inserting into the peritoneal cavity a collodion capsule containing culture was adopted.

In the first experiment the culture used was from the original material of Virus B. IV. The Dog No. 54 was killed after 142 days; the collodion part of the capsule was found ruptured in the centre of a tuberculous tumour in the gastro-splenic omentum and the glass part free in the peritoneal cavity. There was tuberculous disease of the peritoneum, spleen, and kidneys.

Cultures were recovered from the glass part of the capsule and from the tumour. Both strains were found to be identical with the original culture, 12 colonies from a primary culture from the capsule, being individually tested on serum and glycerin serum.

The growth from six of the serum tubes containing 32 mg. was used to feed Dog 82, which was killed 91 days later, and found to be free from tuberculosis.

Dog 92 was fed with 25 mg. of the growth from the corresponding glycerin serum tubes after 68 days incubation. This animal was killed after 64 days and showed tuberculosis of one submaxillary gland, and twelve caseous nodules in the lungs. A culture isolated direct from the lung showed no alteration in character, beyond that due to its residence on glycerin media, and no change in virulence.

In the second experiment the capsule contained the culture isolated from Chimpanzee 8 (Virus B. IV.). The Dog, No. 56, was ill and emaciated when killed. The post-mortem examination showed tuberculosis of the peritoneum and miliary tubercles in the lungs, the capsule, as in the previous experiment, being ruptured and surrounded by a tuberculous tumour. Cultures recovered from the tumour, and from the lung through a guinea-pig, showed no change.

The culture from the tumour was inoculated subcutaneously in a dose of 10 mg. into Dog 74. In this animal, killed after 63 days, there was a local lesion, a tuberculous cavity in the region of the axilla and miliary tuberculosis of the lungs and kidneys. Cultures obtained

from the cavity and from a bronchial gland through a guinea-pig were identical with that from the original material of Virus B. IV.

The culture isolated from the bronchial gland was used to feed Dog 116, in a dose of 10 mg.; the dog was killed after 98 days and showed general tuberculosis of a rather more severe type than that so far produced in dogs by feeding. Cultures have been isolated from a mesenteric gland and three separate lung nodules. Those obtained from the mesenteric gland and two of the lung nodules are identical with that from the original material of Virus B. IV.; the culture from the third lung nodule grows distinctly better and is equal to any in Class III. The virulence of these cultures has not yet been tested.

PIG PASSAGE.

Virus B. I. has been passed through a series of four pigs in succession, all of which developed general tuberculosis. The total period of residence in the animal body was 551 days.

The first animal was fed with tuberculous milk of Cow 40 and an emulsion made from its mesenteric glands was inoculated subcutaneously into two pigs, No. 10 and No. 2.

From the lesions of one of these, No. 12, two more pigs, No. 14 and 16, were inoculated subcutaneously.

The passage was continued with culture obtained from Pig 16; this was inoculated subcutaneously into Pigs 96 and 98 in doses of 0·1 mg. and 1 mg. respectively. Cultures were isolated from all the pigs, and showed in their reactions on the differential media the characters of the original virus.

The virulence of the culture from the last pig of the series was unaltered.

BOVINE PASSAGES.

Three viruses, namely B. I., B. II. and B. IV., have each been passed through a series of bovines, the number of animals being six in the first, three in the second and three in the third series, and the duration of residence 494, 489 and 693 days respectively. There was no evidence of any alteration in virulence, and culture isolated from the different animals in each series were identical with those from the original viruses.

GUINEA-PIG PASSAGE.

Virus B. II. has been passed through a series of 24 guinea-pigs. The first guinea-pig was inoculated with an emulsion from the original material and each of the others with an emulsion of a tuberculous organ of the preceding animal.

The total period of residence in the guinea-pig's body was 3 years 166 days.

Cultures were isolated from three of the guinea-pigs, including the last of the series.

The cultural characters of the three strains were precisely the same as those of other strains of this virus.

This passage experiment shows clearly that residence in the body of the guinea-pig does not alter the characters of the bovine tubercle bacillus.

SUMMARY OF PASSAGE EXPERIMENTS.

Chimpanzees, baboons and monkeys, although peculiarly susceptible to the action of the bovine tubercle bacillus, were chosen for passage experiments on account of their blood relationship to man. In order to approximate as nearly as possible to a natural mode of infection, the bacilli were inoculated by feeding with culture or with milk containing tubercle bacilli. The passages were continued by culture isolated from the preceding animal in order to encourage the more saprophytic bacilli to increase, and with the same object in several cases the cultures were grown on media containing glycerin.

In the chimpanzee passage with Virus B. IV. three animals were used, the total period of residence in the animal body being 348 days and in culture 138 days.

In the chimpanzee passage with Virus B. IX. two animals were used, the total period of residence in the animal body being 179 days and in culture 538 days.

In the baboon and monkey passages the periods during which the bacilli were in the animal body varied from 198 to 361 days.

With one exception the culture recovered from the last animal in each series showed no change in cultural characters and in all instances the virulence for rabbits remained unaltered. The exceptional case occurred in a passage experiment with Virus B. I. through two baboons, the total period of residence of the culture in the animal body being 198 days. The virus primarily used belonged to the most difficult growing class of bovine bacilli, while that recovered from the last animal grew rather better than any of the most easy growing bovine viruses.

The dog exhibits a high degree of resistance to the action of the bovine tubercle bacillus when introduced into the body by subcutaneous inoculation or by feeding. In five instances cultures have been recovered from dogs experimentally inoculated.

Two dogs were fed with Virus B. IV. and Virus B. IX. respectively and were killed after 135 and 111 days; in each case the culture isolated grew more luxuriantly than any bovine virus and was slightly virulent. Moreover, when reinoculated into other dogs they were found to be incapable of causing more than minimal lesions. Three dogs were inoculated with Viruses B. IV. VIII. and XXII. A culture isolated from the latter killed after 156 days showed increased luxuriance without change in virulence, while in the others there was not the least alteration.

The results in the first two cases may be explained on two hypotheses—either the lesions were not due to the bacilli experimentally introduced, or the bacilli introduced were modified by residence in the animal body.

In order to test the latter hypothesis, Virus B. IV. was passed through two series of dogs and Virus B. IX. through one series, the periods in which the bacilli were in contact with the tissues being 206, 237 and 185 days. The results were negative, the cultures isolated from the last animal in each series showing not the least change in cultural characters or virulence.

The passage experiments with pigs (551 days), oxen (498, 489 and 693 days) and guinea-pigs (1,261 days) produced no change of cultural characters or virulence in the viruses used.

Conclusions.

These passage experiments, so far as they have gone, show that the bovine tubercle bacillus is very retentive of its special cultural characters and high virulence.

The results with dogs are suggestive, and the passage experiments are being continued in order to ascertain whether the dog can modify the bovine tubercle bacillus.

A. Stanley Griffith.

TABLE 1.

CHIMPANZEE PASSAGE.

WITH

VIRUS B. IV.

(July 29, 1903.)

CHIMPANZEE 8.

Fed on October 28, 1904, with 107cc. milk of Cow 172 (Table IV. A.) containing ten million tubercle bacilli.

Died of broncho-pneumonia March 21, 1905, 144 days after.

P.M.—Tuberculosis limited to intestines and nearest glands.

CULTURE
derived from a colic gland.

RABBITS

Inoculated with culture from original material.

Number.	Dose.	Method.	Duration of Life.	Result.
6 rabbits	0·1 mg.	Intrav.	D. 21 days (average)	G.T.
117	0·1 mg.	Intrap.	D. 40 days	G.T.
87	0·1 mg.	Subcut.	D. 105 „	G.T.
88	0·1 mg.	„	D. 72 „	G.T.
133	1·0 mg.	„	D. 112 „	G.T.

CHIMPANZEE 10.

Fed on July 16, 1905, with 0·1 mg. of culture from Chimpanzee 8.

Died, November 6, 1905, 113 days later.

P.M.—General tuberculosis.

CULTURE
derived from a mesenteric gland.

RABBITS

Inoculated Nov. 6, 1906, with culture from Chimpanzee 8.

Number.	Dose.	Method.	Duration of Life.	Result.
320	0·1 mg.	Intrav.	D. 16 days	G.T.
321	1·0 mg.	Intrap.	D. 14 „	G.T.
324	0·1 mg.	Subcut.	D. 64 „	G.T.
322	1·0 mg.	„	D. 53 „	G.T.

CHIMPANZEE 16.

Fed on January 5, 1906, with 0·01 mg. of culture from Chimpanzee 10.

Died, April 6, 1906, 91 days later.

P.M.—General tuberculosis.

CULTURE
derived from spleen.

RABBITS

Inoculated Jan. 5, 1906, with culture from Chimpanzee 10.

Number.	Dose.	Method.	Duration of Life.	Result.
658	0·1 mg.	Intrav.	D. 20 days	G.T.
664	0·01 mg.	Intrap.	D. 41 „	G.T.
662	0·1 mg.	„	D. 32 „	G.T.
660	1·0 mg.	„	D. 18 „	G.T.
663	0·01 mg.	Subcut.	D. 100 „	G.T.
661	0·1 mg.	„	D. 85 „	G.T.
659	1·0 mg.	„	D. 96 „	G.T.

CHIMPANZEE 22.

Inoculated subcutaneously on July 4, 1906, with 0·001 mg. of culture from Chimpanzee 16.

Died, September 29, 1906, 87 days later.

P.M.—General tuberculosis.

CULTURE
derived from bronchial gland.

RABBITS.

Inoculated Aug. 4, 1906, with culture from Chimpanzee 16.

Number.	Dose.	Method.	Duration of Life.	Result.
948	1·0 mg.	Intrav.	D. 14 days	G.T.
949	0·1 mg.	„	D. 16 „	G.T.
950	1·0 mg.	Intrap.	D. 9 „	G.T.
951	0·1 mg.	„	D. 42 „	G.T.
954	0·001 mg.	„	K. 54 „	G.T.
955	0·001 mg.	„	D. 45 „	G.T.
952	1·0 mg.	Subcut.	K. 54 „	G.T.
953	0·1 mg.	„	K. 54 „	G.T. (Slight)

CHIMPANZEE 24.

Inoculated subcutaneously on November 21, 1906, with 0·00001 mg. of culture from Chimpanzee 22.

TABLE 2.

CHIMPANZEE PASSAGE.

VIRUS B. IX.

(June 21st, 1904.)

CHIMPANZEE 14.

Fed on September 11th, 1905, with about 1·1 mg. of culture derived from the original material of Virus B. IX.

Died, November 13th, 1905. 63 days later.

P.M.—General tuberculosis; intestines and mesenteric glands severely affected.

RABBITS

Inoculated with culture from the original material.

Number.	Dose.	Method.	Duration of Life.	Result.
212	0·1 mg.	Intrav.	D. 18 days	G.T.
(4 rabbits)	1·0 mg.	Intrap.	D. 22 days (average).	G.T.
211	0·1 mg.	Intrap.	D. 30 days	G.T.
(3 rabbits)	1·0 mg.	Subcut.	D. 69 days (average).	G.T.

CULTURE
derived from an ileo-colic gland.

CHIMPANZEE 18.

Fed on February 12th, 1906, with 0·01 mg. of culture from Chimpanzee 14.

Died, June 8th, 1906. 116 days after.

P.M.—General tuberculosis.

RABBITS.

Inoculated February 12, 1906, with culture from Chimpanzee 14.

Number.	Dose.	Method.	Duration of Life.	Result.
742	1·0 mg.	Subcut.	D. 25 days	S.T.
743	0·1 mg.	Subcut.	D. 103 days	G.T.
744	0·01 mg.	Subcut.	D. 132 days	G.T.
745	0·001 mg.	Subcut.	D. 151 days	G.T.

CULTURE
derived from spleen.

RABBITS.

Inoculated July 14, 1906, with culture from Chimpanzee 18.

Number.	Dose.	Method.	Duration of Life.	Result.
993	1·0 mg.	Intrav.	D. 16 days	G.T.
994	0·1 mg.	Intrav.	D. 18 days	G.T.
996	1·0 mg.	Intrap.	D. 17 days	G.T.
995	0·1 mg.	Intrap.	D. 30 days	G.T.
997	1·0 mg.	Subcut.	K. 44 days	Early G.T.
998	0·1 mg.	Subcut.	K. 44 days	

TABLE 3.

BABOON PASSAGE.

VIRUS B. I.

BABOON 8.

Fed on January 22, 1904, with milk of Cow 64 containing one million tubercle bacilli.

Killed, April 28, 1904, 97 days later.

P.M.—General tuberculosis.

RABBITS

Inoculated with culture obtained from Cows 40 and 44.

Number.	Dose.	Method.	Duration of Life.	Result.
(7 rabbits)	0·1 mg.	Intrav.	22 days (average)	G.T.
137	1·0 mg.	Intrap.	31 days	G.T.
112	0·1 mg.	Intrap.	31 days	G.T.
136	1·0 mg.	Subcut.	82 days	G.T.
3 rabbits	0·1 mg.	Subcut.	95 days (average)	G.T.

CULTURE
derived from cervical gland

RABBIT.

Inoculated with emulsion from cervical gland.

Number.	Dose.	Method.	Duration of Life.	Result.
48	not estimated.	Intrap.	D. 88 days	G.T.

BABOON 64.

Fed on October 13, 1905, with 0·1 mg. of culture from Baboon 8.

Died, January 22, 1906, 101 days later.

P.M.—General tuberculosis.

CULTURE
derived from lung

RABBITS.

Inoculated on May 1, 1906, with culture from Baboon 64.

Number.	Dose.	Method.	Duration of Life.	Result.
857	0·1 mg.	Intrav.	D. 21 days	G.T.
858	1·0 mg.	Intrap.	D. 15 days	G.T.
859	0·1 mg.	Intrap.	D. 16 days	G.T.
860	1·0 mg.	Subcut.	K. 91 days (Dying)	G.T.

TABLE 4.

BABOON PASSAGE.

VIRUS B. IV.

(July 29, 1903.)

BABOON 22.

Fed with tuberculous milk of Cow 172 from September 9, 1904, to October 4, 1904.

Died December 8, 1904, 90 days after the experiment began.

P.M.—General tuberculosis.

CULTURE

derived from a cervical gland.

BABOON 62.

Fed on September 26, 1905, with 0·1 mg. of culture from Baboon 22.

Died, February, 1906, 136 days later.

P.M.—General tuberculosis.

CULTURE

derived from the lung.

RABBITS.

For rabbits inoculated with culture from the original material *see* Table 1.

RABBITS.

Inoculated on May 11, 1906, with culture from Baboon 62.

Number.	Dose.	Method.	Duration of Life.	Result.
874	0·1 mg.	Intrav.	D. 19 days	G.T.
873	0·1 mg.	Intrap.	D. 16 days	G.T.
872	1·0 mg.	Subcut.	K. 108 days	G.T. (slight)

TABLE 5.

RHESUS MONKEY AND BABOON PASSAGE.

VIRUS B. I.

MONKEY 76.

Fed on April 7, 1904, with 0·01 mg. of culture obtained from the supramammary lymphatic gland of Cow 44.

Killed, when dying, November 21, 1905, 228 days later.

P.M.—General tuberculosis.

CULTURE
obtained from the spleen.

RABBITS.

For rabbits inoculated with bovine strains of this virus *see* Table 4.

BABOON 66.

Fed on September 27, 1905, with 0·1 mg. of culture from Monkey 76.

Died, February 7, 1906, 133 days after.

P.M.—General tuberculosis.

CULTURE
derived from spleen.

RABBITS.

Inoculated on February 20, 1905, with culture from Monkey 76.

Number.	Dose.	Method.	Duration of Life.	Result.
189	0·1 mg.	Intrav.	D. 24 days	G.T.
192	1·0 mg.	„	D. 16 „	G.T.
190	1·0 mg.	Intrap.	D. 23 „	G.T.
191	1·0 mg.	„	D. 32 „	G.T.
193	1·0 mg.	Subcut.	D. 47 „	G.T.
194	1·0 mg.	„	D. 63 „	G.T.

RABBITS.

Inoculated on July 6, 1906, with culture from Baboon 66.

Number.	Dose.	Method.	Duration of Life.	Result.
984	1·0 mg.	Intrav.	D. 14 days	G.T.
985	0·1 mg.	„	D. 26 „	G.T.
987	1·0 mg.	Intrap.	D. 12 „	G.T.
986	0·1 mg.	„	D. 1 day	Coccidiosis.

TABLE 6.

RHESUS MONKEY PASSAGE.

VIRUS B. IX.

(June 21, 1904.)

MONKEY 110.

Fed on July 10, 1905, with 1·0 mg. of culture derived from the original material of Virus B IX.

Killed, when dying, September 28, 1905, 80 days later.

P.M.—General tuberculosis.

RABBITS.

For rabbits inoculated from original material *see* Table 2.

CULTURE
derived from an iliac gland.

MONKEY 116.

Inoculated subcutaneously on November 22, 1905, with 1·0 mg. of culture from Monkey 110.

Died, December 28, 1905, 36 days later.

P.M.—Miliary tuberculosis.

MONKEY 114.

Inoculated subcutaneously on November 22, 1905, with 0·01 mg. of culture from Monkey 110.

Died, December 26, 1905, 34 days later.

P.M.—Miliary tuberculosis.

RABBITS.

Inoculated with culture from Monkey 110.

Number.	Dose.	Method.	Duration of Life.	Result.
521	1·0 mg.	Intrap.	D. 22 days	G.T.
522	0·01 mg.	Intrap.	D. 37 „	G.T.

CULTURE
derived from an axillary gland.

MONKEY 130.

Fed on January 24, 1906, with 0·01 mg. of culture from Monkey 116.

Killed when ill, April 20, 1906, 86 days later.

P.M.—General tuberculosis.

MONKEY 132.

Fed on January 24, 1906, with 0·0001 mg. of culture from Monkey 116.

Died, June 7, 1906, 134 days later.

P.M.—General tuberculosis.

RABBITS.

Inoculated on January 24, 1906, with culture from Monkey 116.

Number.	Dose.	Method.	Duration of Life.	Result.
691	1·0 mg.	Subcut.	D. 100 days	G.T.
692	0·01 mg.	„	D. 20 „	S.T.
593	0·0001 mg.	„	D. 100 „	G.T.

MONKEY 152.

Inoculated subcutaneously on June 7, 1906, with a small quantity of emulsion made from the spleen of Monkey 132.

Died, September 26, 1906, 111 days after inoculation.

P.M.—General tuberculosis.

RABBIT.

Inoculated intraperitoneally with an emulsion made from a splenic lymphatic gland.

Number.	Duration of Life.	Result.
1039	D. 75 days	G.T.

RABBITS.

Inoculated on July 27, 1906, with culture derived from the bronchial gland of Monkey 132.

Number.	Dose.	Method.	Duration of Life.	Result.
1022	1·0 mg.	Intrav.	D. 5 days	—
1019	0·1 mg.	Intrav.	D. 16 days	G.T.
1020	0·1 mg.	Intrav.	D. 21 days	G.T.
1021	1·0 mg.	Intrap.	D. 23 days	G.T.
1023	0·1 mg.	Intrap.	D. 5 days	—

TABLE 7.

MONKEY AND BABOON PASSAGE.

VIRUS B. IX.

(June 21, 1904.)

MANGABEY MONKEY 4.

Fed on June 2, 1905, with 1·0 mg. of culture derived from the original material of Virus IX.

Killed, August 25, 1905, 84 days later.

P.M.—General tuberculosis.

CULTURE
derived from a lumbar gland.

MANDRILL BABOON 68.

Fed on October 13, 1905, with 0·1 mg. of culture from Mangabey 4.

Died, November 28, 1905, 46 days later.

P.M.—Tuberculosis limited to a retro-pharyngeal gland.

CULTURE
derived from the pharyngeal gland.

MONKEY 126.

Fed on January 24, 1906, with 0·01 mg. of culture from Baboon 68.

Died, May 24, 1906, 126 days later.

P.M.—General tuberculosis.

CULTURE.
derived from spleen.

MONKEY 128.

Fed on January 24, 1906, with 0·0001 mg. of culture from Baboon 68.

Killed, July 12, 1906, 169 days later.

P.M.—No tuberculosis.

RABBITS.

For rabbits inoculated with culture from the original material *see* Table 2.

RABBITS.

Inoculated on January 24, 1906, with culture from Baboon 68.

Number.	Dose.	Method.	Duration of Life.	Result.
688	1·0 mg.	Subcut.	D. 77 days	G.T.
689	0·01 mg.	„	D. 129 days	G.T.
690	0·0001 mg.	„	K. 187 days	G.T.

RABBITS.

Inoculated on July 27, 1906, with culture from Monkey 126.

Number.	Dose.	Method.	Duration of Life.	Result.
1016	1·0 mg.	Intrav.	D. 15 days	G.T.
1015	0·1 mg.	Intrav.	D. 19 days	G.T.
1018	0·1 mg.	Intrav.	D. 25 days	G.T.
1014	1·0 mg.	Intrap.	D. 5 days	—
1017	0·1 mg.	Intrap.	D. 28 days	G.T.

TABLE 8.

LEMUR PASSAGE.

VIRUS B. IX.

(June 27, 1904.)

LEMUR 2.

Fed June 2, 1905, with 1·0 mg. of culture derived from the original material of Virus B. IX.

Killed, July 18, 1905, 46 days after.

P.M.—General tuberculosis.

CULTURE
derived from a mesenteric gland.

LEMUR 12.

Inoculated subcutaneously on November 24, 1905, with 1·0 mg. of culture from Lemur 2.

Killed, dying, December 17, 1905, 23 days after.

P. M. — Local abscess, caseation of nearest glands and early tuberculosis of the spleen.

LEMUR 10.

Inoculated subcutaneously on November 24, 1905, with 0·01 mg. of culture from Lemur 2.

Died, December 24, 1905, 30 days after.

P. M. — Local lesion, caseation of nearest glands, a few tubercles in spleen, liver, and lungs.

RABBITS.

For rabbits inoculated with culture from original material, *see* Table 2.

RABBITS.

Number.	Dose.	Method.	Duration of Life.	Result.
535	1·0 mg.	Intrav.	D. 14 days	G.T.
536	0·1 mg.	„	D. 21 „	G.T.
537	1·0 mg.	Intrap.	D. 18 „	G.T.

TABLE 9.

DOG PASSAGE.

VIRUS B. IV.

(July 29, 1903.)

DOG 54.

A collodion capsule containing an emulsion of culture derived from the original material of Virus B. IV. was inserted into the peritoneal cavity on May 20, 1905.

The dog was killed on October 9, 1905, 142 days later.

P.M.—The capsule was found ruptured and surrounded by a tumour, and there was tuberculosis of the peritoneum, spleen and kidneys.

CULTURE
raised from the interior of the capsule.

DOG 92.

Fed on January 22, 1906, with 25 mg. of culture from Dog 54.

(The culture used was a glycerine serum culture and was 68 days old.)

Killed, March 27, 1906, 64 days after.

P.M.—Tuberculosis of one submaxillary gland: about 12 caseous nodules in the lung.

CULTURE
derived from the lung.

RABBITS.

Inoculated on July 18, 1906.

Number.	Dose.	Method.	Duration of Life.	Result.
1009	1·0 mg.	Intrav.	D. 14 days	G.T.
1010	0·1 mg.	Intrav.	D. 21 days	G.T.
1013	1·0 mg.	Intrap.	D. 20 days	G.T.
1011	0·1 mg.	Intrap.	D. 26 days	G.T.
1012	1·0 mg.	Subcut.	K. 40 days	G.T. (slight)

DOG 82.

Fed on December 15, 1906, with 32 mg. of culture from Dog 54.

(The culture used was a serum culture and was 30 days old.)

Killed, March 16, 1906, 91 days after.

P.M.—There were some doubtful tubercles in the kidneys and one doubtful nodule in the lung (not apparently tuberculous).

TABLE 10.

DOG PASSAGE.

VIRUS B. IV.

DOG 56.

A collodion capsule containing culture from Chimpanzee 8 was inserted in the peritoneal cavity on June 8, 1905.

The dog was killed on August 23, 1905, 76 days after.

P.M.—The capsule was found ruptured and surrounded by a tumour; there was peritoneal tuberculosis and miliary tuberculosis of the lungs.

CULTURE
obtained from the tumour.

DOG 74.

Inoculated subcutaneously on October 13, 1905, with 10 mg. of culture from Dog 56.

Killed, December 15, 1905, 63 days later.

P.M.—Local lesion; fairly numerous grey miliary tubercles in the lungs; a few tubercles in the kidneys.

CULTURE
derived from a bronchial gland (normal to the eye) through Guinea-pig 1808, January 26, 1906.

DOG 116.

Fed on March 29, 1906, with 10 mg. of culture from Dog 74.

Killed, July 5, 1906, 98 days later.

P.M.—Tuberculosis of pharyngeal, cervical and mesenteric glands, liver, lungs and bronchial glands.

RABBIT.

Inoculated with emulsion of lung of Dog 116 (very small dose).

Number.	Method.	Duration of Life.	Result.
971	Intrap.	K. 52 days	Very slight tub'rc'los's

TABLE II.

DOG PASSAGE.

VIRUS B. IV.

(July 29, 1903.)

DOG 18.

Fed on August 23, 1904, with emulsion made from organs of Guinea-pigs 1148 and 1150, inoculated with milk of Cow 164.

Dose : 10·15 million tubercle bacilli.

Killed, January 5, 1905. 135 days later.

P.M.—Tuberculosis of two mesenteric glands and a few doubtful tubercles in the lungs.

RABBITS.

For rabbits inoculated with culture from original material *see* Table I.

CULTURE
derived from a mesenteric gland.

DOG 132.

Fed on June 1, 1906, with 50 mg. of culture derived from Dog 18.

Killed, August 17, 1906. 77 days later.

P.M.—Caseous focus in a pharyngeal gland; caseous patches and foci in the mesenteric glands; two tubercles in the lungs and a caseous focus in each bronchial gland.

RABBITS.

Inoculated with culture from Dog 18.

Number.	Dose.	Method.	Duration of Life.	Result.
410	0·1 mg.	Intrav.	K. 97 days	A few T.'s in lungs and kidneys.
890	10· mg.	Intrap.	K. 83 days	A few T.'s on peritoneum, in lungs and kidneys.
409	1·0 mg.	Intrap.	K. 97 days	A few T.'s on peritoneum, in lungs and kidneys.
411	0·1 mg.	Intrap.	D. 68 days	A few T.'s on peritoneum and in lungs.
408	1·0 mg.	Subcut.	K. 97 days	Local lesion, 2 nodules in lung.
412	0·1 mg.	Subcut.	K. 97 days	Ulcerated local lesion, 1 nodule in lung.

TABLE 12.

DOG PASSAGE.

VIRUS B. IX.

(June 21, 1904.)

DOG 60.

Fed on July 10, 1905, with 1·0 mg. of culture derived from the original material. Killed, October 30th, 112 days after.
P.M.—Retrogressive tuberculosis of pharyngeal, mesenteric and ileo-colic glands.

CULTURE
derived from a mesenteric gland.

DOG 84.

Fed on January 2, 1906, with 50 mg. of culture originating from a number of primary colonies.

Killed, March 16, 1906, 73 days later.

P.M.—There were a few miliary tubercles in the lungs, and no disease elsewhere.

CULTURE
derived from the lung.

RABBITS.

Inoculated on July 17, 1906, with culture from Dog 84.

Number.	Dose.	Method.	Duration of Life.	Result.
1003	1·0 mg.	Intrav.	D. 17 days	G.T.
1000	0·1 mg.	„	D. 23 „	G.T.
1001	1·0 mg.	Intrap.	D. 21 „	G.T.
1002	0·1 mg.	„	D. 32 „	G.T.
999	1·0 mg.	Subcut.	K. 111 „	G.T. (slight).

RABBITS.

Inoculated with culture originating from a number of primary colonies.

Number.	Dose.	Method.	Duration of Life.	Result.
637	0·1 mg.	Intrav.	D. 28 days	G.T.
639	1·0 mg.	Intrap.	D. 28 „	G.T.
638	0·1 mg.	„	D. 25 „	G.T.
640	1·0 mg.	Subcut.	D. 161 „	G.T.
641	0·1 mg.	„	D. 78 „	G.T.

RABBITS.

Inoculated with cultures originating from single primary colonies. Dose in each case=the growth from one glycerin agar tube.

Number of Rabbit.	Number of Colony.	Method.	Duration of Life.	Result.
729	1	Subcut.	D. 90 days	G.T.
730	2	„	K. 105 „	G.T.
731	3	„	K. 90 „	G.T.
732	4	„	D. 88 „	G.T.

DOG 130.

Inoculated subcutaneously and intraperitoneally on May 17, 1906, with 48 mg. of culture originating from a single primary colony.

Died, August, 1906, 85 days after inoculation.

P.M.—General tuberculosis.

RABBITS.

Inoculated intraperitoneally with an emulsion from the liver.

Number.	Duration of Life.	Result.
1029	K. 55 days.	G.T.
1030	D. 14 days	S.T.

TABLE 13.

DOG PASSAGE.

VIRUS B. IX.

(June 21, 1904.)

DOG 50.

Fed on June 2, 1905, with 1·0 mg. of culture derived from the original material of Virus B IX.

Killed, September 21, 1905, 111 days later.

P.M.—Tuberculosis of one lobe of the lung, and (?) of the kidneys.

LUNG

GUINEA-PIG 1707.

Inoculated September 21, 1905.

Died October 21, 1905 (30 days).

P.M.—General tuberculosis.

CULTURE

7th generation, 20 days old.

DOG 108.

Fed on March 21, 1906, with 10 mg. of culture.

Killed, June 27, 1906, 98 days after.

P.M.—One miliary tubercle in the lungs; no sign of tuberculosis elsewhere.

DOG 110.

Inoculated subcutaneously on March 21, 1906, with 10 mg. of culture.

Killed, June 28, 1906, 99 days after inoculation.

P.M.—Small healing ulcer; two grey tubercles in the lungs.

GUINEA-PIG 1708.

Inoculated September 21, 1905.

Died October 18, 1905 (27 days).

P.M.—General tuberculosis.

CULTURE

3rd generation, 20 days old.

CALF 374.

Inoculated subcutaneously on January 2, 1906, with 50 mg. of culture.

Killed April 3, 1906, 91 days later.

P.M.—Caseous local lesion; caseation of nearest glands; a few tubercles in the portal, thoracic, coeliac and ileo-colic glands and the lungs.

CALF 394.

Inoculated subcutaneously on April 3, 1906, with an emulsion from the prescapular gland of Calf 374.

Number of tubercle bacilli.

Killed, June 6, 1906, 64 days after inoculation.

P.M.—Local lesion only.

RABBITS.

For rabbits inoculated with culture from the origi material, *see* Table 2.

RABBITS.

TABLE 15.

PIG PASSAGE.

VIRUS B I.

(May 6, 1902.)

PIG 8.

Fed with milk of Cow 40 for 92 days.

Killed, June 4, 1903, 247 days after the experiment began.

P.M.—Two or three caseous nodules in the small intestine, not ulcerated; enlarged and caseous mesenteric glands; slight tuberculosis of lungs, thoracic glands and liver.

Emulsion of mesenteric glands.

PIG 10.

Subcutaneous.

Dose: 10 cc. (no T.B. found).

Killed, October 8, 1903 (126 days).

P.M.—Small local lesion; adjoining glands caseous and calcareous; tuberculosis of all the organs except the spleen.

PIG 12.

Subcutaneous.

Dose: 10 cc. (no T.B. found).

Killed, October 3, 1903 (121 days).

P.M.—Caseous local lesion; neighbouring glands caseous and calcareous; general tuberculosis.

CALF 104.

Subcutaneous.

Dose: 10 cc. (no T.B. found).

Killed. September 11, 1903 (99 days).

P.M.—Calcareous tubercles at seat of inoculation; calcareous prescapular gland; tubercles in liver, spleen, lungs, thoracic and two mesenteric glands.

CALF 106.

Subcutaneous.

Dose: 10 cc. (no T.B. found).

Killed, September 12, 1903 (100 days).

P.M.—Calcareous tubercles at seat of inoculation; prescapular gland caseous and calcareous. One calcareous tubercle in a mediastinal gland.

Emulsion of inguinal and hepatic glands and spleen.

PIG 14.

Subcutaneous.

Dose: 9,000 T.B.

Killed, January 25, 1904, (114 days).

P.M.—Small ulcerated fibro-caseous lesion; enlargement and caseation of inguinal, iliac, and gastric glands; a few tubercles in liver, about 30 in each lung; spleen unaffected; bronchial glands tuberculous.

PIG 16.

Subcutaneous.

Dose: 9,000 T.B.

Killed, January 16, 1904, (105 days).

P.M.—Ulcerated local lesion; enlargement and caseation of inguinal, iliac, and gastric glands; numerous tubercles in liver, spleen, lungs, and bronchial glands; tubercles on the diaphragm, pleura and meso-testis.

CALF 124.

Subcutaneous.

Dose: 9,000 T.B.

Died, December 12, 1903 (71 days).

P.M.—General tuberculosis.

CALF 130.

Subcutaneous.

Dose: 9,000 T.B.

Killed, January 15, 1904. (104 days).

P.M.—Small calcareo-caseous tumour; adjacent glands tuberculous; slight tuberculosis of liver, spleen, lungs and thoracic glands.

Culture.

PIG 98.

Subcutaneous.

Dose: 1·0 mg.

Died, March 29, 1905, (78 days).

P.M.—Small local lesion; one inguinal gland partly caseous; a few tubercles in the liver and spleen, and numerous tubercles in the lungs which showed areas of consolidation; tuberculosis of pleura and diaphragm.

PIG 96.

Subcutaneous.

Dose: 0·1 mg.

Killed, September 7, 1905, 240 days after.

P.M. — Small caseous lesion; neighbouring glands caseous; spleen contained three miliary tubercles, the liver numerous caseous nodules and the lungs sparsely scattered hard tubercles; the thoracic and several of the abdominal glands, and two glands in the neck were tuberculous.

CALF 230.

Subcutaneous.

Dose: 50 mg.

Died, February 13, 34 days after inoculation

P.M.—General tuberculosis.

DETAILED DESCRIPTION OF EXPERIMENTS.

CHIMPANZEE PASSAGE.

VIRUS B. IV.

CHIMPANZEE 8.*

Fed on October 25th, 1904, with 107 c.c. milk of Cow 172, containing approximately 10,000,000 tubercle bacilli.

Died of broncho-pneumonia, March 21st, 1905. 144 days later.

Abstract of Post-Mortem Notes.

Pharynx and Glands in Neck normal ; the small intestine showed five tuberculous ulcers, varying from 3 to 4 mm. up to 2 cm. in diameter. Nine of the mesenteric glands were slightly enlarged and contained dense fibroid nodules, caseous in the centre and appreciably gritty from calcification. In the meso-colon there were three enlarged glands, close together ; two were caseous throughout and slightly gritty, the third was partly caseous. There was an abscess (not tuberculous) in the wall of the abdomen and broncho-pneumonic patches in the lungs.

A culture was isolated from one of the colic glands and inoculated into a series of six rabbits and chimpanzee 10 (by feeding).

Two of the rabbits died prematurely ; the rest died of general tuberculosis in periods varying from 16 to 64 days.

CHIMPANZEE 10.

(SECOND CHIMPANZEE PASSAGE OF VIRUS B. IV.)

Fed with culture derived from a colic gland of Chimpanzee 8.

Dose.—0·1 milligramme (4th generation, 24 days old).

Date.—July 16th, 1905.

Weight.—July 18th, 1905. 11 lbs. 14 ozs.

Died.—November 6th, 1905. 113 days after the experiment began.

Clinical History.

Temperature.—The temperature during the first six weeks varied between 37° and 38·4°, with the exception of two rises each to 39·1° on the twentieth and fortieth days respectively. On August 27th (42 days after feeding) there was a sudden rise of temperature to 40·3° C., and a rapid fall on the next day to 36·5° C. The temperature rapidly rose again, and varied for about a fortnight between 37·9° and 39·3° ; it then gradually became more and more irregular, and in the month of October showed considerable fluctuations, on several occasions rising more than 2°, and on two falling more than 3° C. (highest temperature 39°C.). In the last few days of life no temperature was recorded.

With the rise of temperature on August 27th the Chimpanzee was a little seedy for a day or two (loss of appetite, and depression) ; he recovered, but remained somewhat anæmic. During the month of October he gradually lost flesh and strength, and became extremely anæmic.

In the last week of life weakness and emaciation were extreme, and the eyelids in the morning were very œdematous.

No diarrhœa was noticed during the experiment, and there was no increase in respiration. On one occasion only was he heard to cough.

Weights.—During the first week there was a gain of 10 ozs. ; then for a fortnight the weight was stationary ; subsequently the animal steadily lost weight, at first slowly, then rapidly.

July 18th, 1905	11 lbs. 14 ozs.
July 25th, 1905	12 lbs. 8 ozs.
August 1st, 1905	12 lbs. 8 ozs.
August 8th, 1905	12 lbs. 8 ozs.
September 12th, 1905	12 lbs. 2 ozs.
October 5th, 1905	12 lbs. 0 ozs.
October 10th, 1905	11 lbs. 14 ozs.
October 24th, 1905	11 lbs. 0 ozs.
November 6th, 1905	9 lbs. 12 ozs.
Loss in weight on the original weight	2 lbs. 2 ozs.
Average loss per week from August 8th to November 6th	3·43 lbs.

* In the majority of these experiments the first animal of the series belongs to one or other of the feeding experiments and a full description of the post-mortem results will be found in Volume I. ; for convenience of reference a short abstract of the notes of these animals is given at the beginning of each series.

Dead.

Post-Mortem Examination.

Body.—Emaciated.

Tongue, Tonsils, Pharynx, Submental Glands, Submaxillary Glands, Parotid Glands, Retro-pharyngeal Glands.—Normal.

Cervical Glands.—Left upper cervical: one enlarged gland showed irregular caseous areas replacing most of the cortex; two smaller glands contained yellowish white softened nodules, each the size of a wheat grain.

Left lower cervical glands normal.

Right upper cervical; one showed in the cortex two softened caseous nodules, each 2 mm. in diameter; the others were normal.

Right lower cervical glands normal.

Abdomen.

Peritoneum.—There was a slight excess of fluid in the peritoneal cavity

Omentum.—The omentum along its attachment to the stomach was œdematous: it contained minute scattered pearly grey tubercles.

Stomach.—Normal.

Small Intestine.—The wall of the intestine was reduced in thickness, and in the situations of some of the larger ulcers presented saccular dilatations. The mucous membrane showed about fifty ulcers distributed along the whole length of the gut, the first situated five inches from the pylorus; twenty-five of these were large, ranging from 1 by 1 cm. to about 2·5 by 2 cm. in area (the latter almost completely encircled the gut); the rest were quite small.

The margins of the ulcers were raised, and the bases slightly thickened and fibrous, showed on the serous surface in many cases an eruption of hard raised tubercles, some pearly grey, others slightly opaque in the centre. In the larger ulcers the floors were irregular and somewhat nodular. None of the ulcers showed caseous deposit, but in some a few minute opaque foci were seen in the base and under the surrounding mucous membrane.

Around many of the larger ulcers there were numerous small ulcers; these in some cases had united with the large ulcer, causing the latter to have a sinuous outline.

Some of the Peyer's patches in the ileum were not uniformly ulcerated, but showed a number of small irregular ulcers, the mucous membrane between which was raised and thickened.

Large Intestine.—Showed one small ulcer, with slightly thickened margin and thin base; no subperitoneal tubercles.

Gastric Glands.—A small gland near the pylorus contained a soft white caseous nodule 1·5 mm. in diameter; the rest were normal.

Mesenteric Glands.—The mesenteric glands were all much enlarged; those in the upper part of the mesentery were fused together, and formed a firm nodular mass 1¾ in. by 1¼ in. by (about) 1 in.; the glands in the lower part of the mesentery were more or less moveable. On section through the large mass all the glands were seen to be caseous throughout and partially softened. They had thick fibrous capsules, which adhered together. The mesentery between this mass and the intestine was œdematous. The glands in the lower part of the mesentery were similarly affected; the caseated tissue was opaque, whitish, firm in most cases, but in some beginning to soften.

Around the margins of the mass of caseated glands were several œdematous glands, one of which contained a caseous focus.

Ileo-Colic Glands.—At the junction of the ileum and the colon there was a group of enlarged glands, some of which were normal on section, whilst others showed the substance replaced to a greater or lesser extent by opaque white caseated tissue, in one or two cases beginning to break down; one gland, the size of a large pea, was caseous throughout.

Colic Glands.—One colic gland contained a soft white caseous tubercle the size of a millet seed; another, the size of a small pea, was caseous nearly throughout. Other colic glands along the margin of the bowel appeared somewhat enlarged, but were not otherwise abnormal.

Spleen.—Was much enlarged (4½ in long by 1¾ in. broad), and was adherent to the wall of the abdomen at the level of the costal cartilages by a tough fibrous adhesion. On the surface were fairly numerous filmy grey tubercles, the largest a little over 1·5 mm. in diameter. On section the pulp contained moderately numerous spherical tubercles, each about one millimetre in diameter, with yellow softened centres and grey translucent margins. There were besides two or three soft caseous nodules with fibrous margins, the largest the size of a wheat grain.

Liver.—The substance was firm but very pale. On the surface were a few minute pearly grey foci, one of which was definitely raised above the surface. On section a few doubtful yellow points were seen.

Hepatic Lymphatic Glands.—A small gland on the duct from the gall bladder contained an opaque white pin-head sized tubercle. Two small glands on the common bile duct were normal.

Kidneys.—Were extremely pale; the capsules stripped readily. The left kidney showed on the surface about half a dozen slightly raised almost transparent tubercles, the largest about one millimetre in diameter. The right kidney showed a few similar tubercles.

Suprarenal Bodies.—Normal.

Pancreatic Glands.—On the upper border of the pancreas, near the duodenum, there was a small gland with a pin-head sized caseous tubercle. Three others further along the pancreas, each the size of a pea, were almost entirely composed of dense opaque white, or yellowish-white, caseated tissue.

Below the head of the pancreas there was a number of glands, ranging in size from a small pea to that of a swallow's egg; some of these were practically caseous throughout, others were partly caseous.

Lumbar Glands.—One on the right side, the size of a large pea, was indurated and extensively caseated; two or three other small glands contained each a caseous tubercle.

Thorax.

Pleura.—The parietal pleura was normal; the lymphatic fringes around the tendon of the diaphragm were slightly hypertrophied.

Lungs.—Were mottled with irregular purplish patches of congestion (pieces floated in water), and were closely and evenly beset with firm nodules, ranging in size from a pin's head to a small pea; the nodules were grey and translucent, the small ones showing a minute central opacity, the larger ones scattered opaque yellowish white points; some of the larger nodules were homogeneous throughout.

Bronchial Glands.—Were perhaps a little enlarged, but there were no foci of caseation.

The tissues of the posterior mediastinum were œdematous.

Heart.—The pericardial sac contained a quantity of clear serous fluid; the heart muscle and valves were normal.

Testicles.—Normal.

Iliac Glands, Inguinal Glands, Axillary Glands.—Normal.

Brain.—Normal.

Microscopical Examination.

Spleen.—Two tubercles were examined; no tubercle bacilli were seen, but there were a few organisms stained blue.

Left Superior Cervical Gland.—Two tubercle bacilli.

Pancreatic Gland.—Numerous tubercle bacilli.

Animals Inoculated.

With Tissue Emulsion.

Two guinea pigs, No. 1768 and 1769, were inoculated with an emulsion made from the lung; two, Nos. 1770 and 1771, from a mesenteric gland, and one, No. 1772, from the spleen; all died of general tuberculosis in periods varying from 15 to 40 days.

With Culture.

Seven rabbits inoculated with culture derived from a mesenteric gland died of general tuberculosi .

CHIMPANZEE 16.

Fed with culture from Chimpanzee 10.

Dose—0·01 milligramme.

Date—January 5th, 1906.

Weight—24 lbs. 10 ozs.

Died—April 6th, 1906. 91 days after the experiment began.

Clinical History.

The chimpanzee was seedy for the first three or four days, with diarrhœa and loss of appetite; the indisposition appeared after, and was probably due to the inoculation of tuberculin (2 cc.) on the day previous to the experiment.

The chimpanzee then remained in good health until about January 27, 1906, when she caught cold, probably from the attendant who was suffering from nasal catarrh at that time. During the next few days the chimpanzee lost appetite and ate nothing but fruit, and there was a constant discharge of muco-pus from the nostrils. Towards the end of this illness a cough developed and numerous râles and rhonchi were heard in the chest.

On February 5, 1906, she began to improve, and the appetite returned, but for a day or two there was still a hoarse cough.

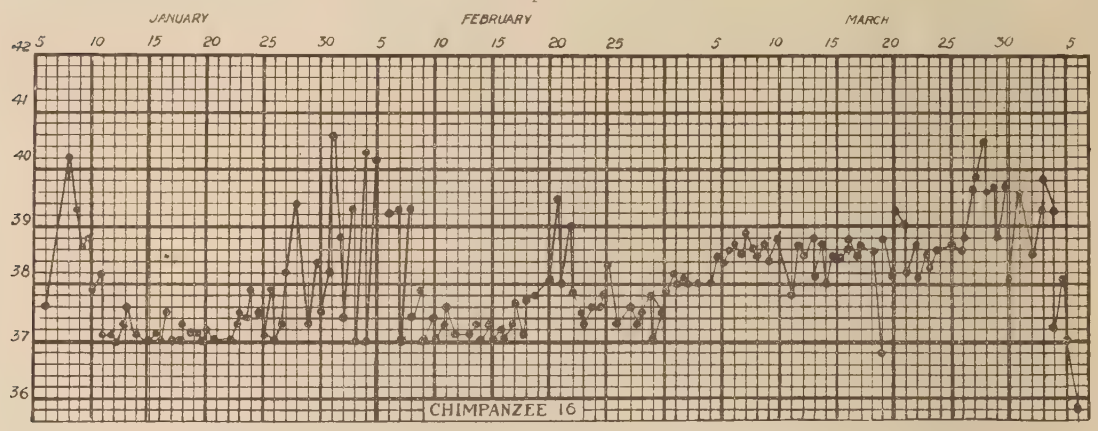
She remained well until March 12, 1906, when for a week she took scarcely any food in the morning and was much quieter than usual. She soon became obviously ill and gradually lost flesh and strength; she showed an increasing disinclination to exert herself and lay most of the day on her back.

On April 5, 1906, she was very weak and languid; respirations were not increased, but were accompanied in expiration by wheezing, probably from hypostatic congestion. She died on April 6, 1906, 91 days after she was fed.

Weights.

January 8th, 1906	-	-	24 lbs. 0 ozs.
January 25th, 1906	-	-	25 lbs. 2 ozs.
February 6th, 1906	-	-	24 lbs. 2 ozs.
February 21st, 1906	-	-	25 lbs. 8 ozs.
March 20th, 1906	-	-	24 lbs. 4 ozs.
April 6th, 1906	-	-	19 lbs. 4 ozs.
Loss in weight	-	-	4 lbs. 12 ozs.

Temperature.



POST-MORTEM EXAMINATION.

Body.—In fair condition but thinner than at beginning of experiment; moderate amount of fat in subcutaneous tissues.

Tongue, Tonsils and Pharynx.—Normal.

Submental, Submaxillary and Parotid Lymphatic Glands.—Normal.

The Right Pharyngeal Gland.—The size of a French bean, showed about three-quarters of its substance yellow, caseous and softened.

The Left Pharyngeal Gland was normal.

Cervical Glands.—On the right side one in the middle of the neck contained two yellow caseous miliary tubercles; the rest were normal. On the left side two small glands in the middle of the neck contained each a soft caseous nodule 1 to 1·5 mm. in diameter; other glands on this side were normal.

Abdomen.

There was a quantity of blood-stained serous fluid in the peritoneal cavity.

The Omentum.—Was moderately fatty and contained fairly numerous grey tubercles, somewhat irregular in outline, the largest a little over 1 mm. in diameter; most of these were translucent throughout, but a few were slightly opaque in the centre; there were besides a few larger ones with soft caseous centres.

Peritoneum.—The peritoneum covering the diaphragm and the lower ribs on the left side was covered with flattened grey tuberculous growths, forming on the tendinous part of the diaphragm an almost continuous layer and showing here and there opaque foci; elsewhere the parietal peritoneum was somewhat roughened, mainly on the left side, and showed one or two small tubercles with caseous centres.

On the meso-colon there were sparsely scattered miliary caseous tubercles.

The appendices epiploacæ were devoid of fat and along the first parts of the colon contained a varying number of hard grey tubercles, most of which were caseous in the centre.

Stomach.—Mucous membrane covered with mucus and partly digested; otherwise normal.

Small Intestine.—The duodenum below the pancreas was closely adherent to the enlarged mesenteric glands and along its mesenteric attachment was thickened and caseating; all the coats were infiltrated except the mucous which was not ulcerated.

The mucous membrane of the small intestine in the upper part was normal except for a flattened caseous nodule, about 5 mm. in diameter, with a small central ulcer.

About three feet from the pylorus there were two tuberculous ulcers close together, one nearly 1 cm. in diameter, the other smaller and more transverse; under the mucous membrane around the ulcers there were a few small caseous nodules, extending chiefly in a lateral direction. On the serous surface opposite these ulcers and for a good distance around them there was an eruption of caseating miliary tubercles.

Most of the Peyer's patches, from about the middle of the small intestine to its termination, were affected; five contained each a typical tuberculous ulcer with raised irregular caseous margins and slightly thickened fibroid base; on the serous surface opposite there were two or three hard tubercles; the ulcers varied from 4 to about 15 mm. in greatest diameter, the one in the terminal patch being larger and more irregular than the others; in the latter patch besides the ulcer there was a slightly raised yellow caseous nodule, the size of a split pea, with a central ulcer. The other affected Peyer's

patches contained from one to six yellow caseous nodules, ranging in size from 3 to 6 mm. in diameter; these resembled the ulcerated nodule in the terminal patch. Another patch contained one minute tubercle.

Large Intestine.—The mucous membrane showed numerous small hæmorrhages but no ulcers or nodules.

Gastric Glands.—Præcardiac glands normal. A gland in the lesser curvature of the stomach contained one soft yellow caseous nodule, 5 mm. in diameter and two small caseous tubercles; a smaller gland contained a miliary caseous tubercle.

Mesenteric Glands.—The mesenteric glands were much enlarged. In the upper part of the mesentery they were fused together to form a tumour, measuring 3 by 2 by 3¾ in. closely adherent at one part to the duodenum; the mass was nodular around the margins and showed on the peritoneal surface numerous slighty raised grey tubercles, the larger of which were slightly opaque in the centre; on section the glands were caseous and softened throughout and had thickened capsules. In the lower part of the mesentery there was a smaller mass, measuring 1½ by ¾ by ¾ in., the glands composing which were more or less moveable one over the other; on section they consisted of softened caseous material with a slightly greenish tinge. Between this mass and the ileo-colic glands there were two slightly enlarged glands each of which contained an irregular softened caseous nodule, the largest 4 mm. in diameter.

Ileo-colic Glands.—On one side of the junction of the ileum and cœcum there was a mass of glands measuring 1½ by 1 by ¾ in.; all these were caseous and softened throughout with the exception of a few small œdematous glands at one extremity which were not obviously tuberculous.

On the opposite side of the cœcum at the root of the appendix there was a group of three small glands; two were entirely caseous, the third contained discrete caseous tubercles.

Colic Glands.—Three colic glands, two on the ascending and one on the descending colon, were caseous and softened throughout; they ranged in size from a small to a large pea; all the other numerous small glands along the large intestine were normal.

The Cœliac and Lumbar Glands.—Were much enlarged, and formed an irregular mass situated between the pancreas and the vertebral column; the lumbar glands were all caseous throughout, whilst some of the cœliac glands were only partly caseous.

In close contact with the upper border of the head of the pancreas, there were two enlarged glands; the larger one contained several soft yellow caseous nodules, and some small tubercles; the smaller one showed an irregular caseous patch replacing about a quarter of the substance.

Spleen.—The spleen was much enlarged, measuring 5½ in. by 2½ in. by about 1 in. in greatest thickness. Projecting from the surface were numerous yellow nodules ranging in size from 1 to 5 or more millimetres in diameter; most of these were surrounded by broad, deeply congested, fibrinous fringes. On section the pulp was firm and dark red, and showed numerous soft yellow caseous nodules, up to 2 or 3 mm. in greatest diameter; these nodules were very irregular in outline, and in several places had coalesced or formed small groups; besides the yellow nodules there were numerous greyish tubercles, some just visible to the eye.

Splenic Lymphatic Glands.—One gland in the hilum of the spleen contained two or three irregular caseous tubercles; another showed a few caseous foci.

The Liver.—Was enlarged, soft and of a pale yellowish colour; on the surface there were numerous slightly raised, flattened tubercles, ranging from about 1 to 2 mm. in diameter; the smaller tubercles were transparent and glassy; the medium sized ones had minute opaque centres, whilst the larger ones were distinctly yellow in the centre. On section small caseous tubercles, the largest about 1 mm. in diameter were sparsely scattered throughout the substance; the cut surfaces showed also numerous transparent grey points.

Portal Glands.—In the portal fissure there were two glands, ranging in size from a pea to a kidney bean; one was caseous throughout; the other contained soft, caseous nodules.

The Kidneys.—Were very pale and appeared to be enlarged; each showed on the surface scattered punctiform hæmorrhages, and four or five miliary tubercles with irregular caseous centres and ill-defined grey margins; no tubercles were seen on section.

Suprarenal Bodies.—Normal.

Thorax.

Heart.—The pericardial sac contained a small quantity of blood-stained fluid; the pericardium was normal. The heart muscle under the pericardium was deeply hæmorrhagic; endocardium normal.

Pleura.—On the pleural surface of the diaphragm, on the left side, there were four flattened caseating nodules, the largest 3 mm. in diameter; the pleura on the muscular part of the diaphragm was covered with minute grey granules. Costal pleura normal.

Lungs.—The left upper lobe was slightly adherent to the chest wall; the lobes of each lung were adherent to each other by old fibrous adhesions. The ventral part of the left upper lobe was firm, dark red, and airless, and there were some red hepatised patches around the roots of the right middle and the left lower lobes; with these exceptions the lungs were crepitant. The lung tissue contained sparsely scattered hard tubercles, ranging in size from about 0·5 to 3 mm. in diameter; the tubercles showed a small amount of central caseation.

Bronchial Glands.—On the right side, one above the bronchus contained an irregular caseous tubercle, 1·5 mm. in diameter; others on this side were normal. On the left side one small gland above the bronchus showed a minute caseous tubercle; a gland below the bronchus on this side contained two miliary caseous tubercles; the rest appeared normal.

Under the pleura in the last interspace near the vertebræ, there was a soft caseating mass, the size of a broad bean.

Brain and Meninges.—Normal.

Various Lymphatic Glands.

One Right Iliac Gland was slightly enlarged, and partly caseous; other iliac glands were normal.

Inguinal Glands.—On the right side one contained two soft, yellow caseous nodules, 3 and 5 mm. in diameter; another contained a minute caseous tubercle; on the left side one contained a soft caseous nodule, 2 mm. in diameter; the rest were normal.

Axillary Glands.—Three glands on the right side contained each a miliary caseous tubercle; another contained a small soft caseous nodule. A gland on the left side was slightly enlarged and showed more than half its substance caseous and softened; other glands in this group appeared normal.

Microscopical Examination (Smear Preparations).

Nodule in Omentum.—Tubercle bacilli moderately numerous.

Inguinal Gland.—Tubercle bacilli moderately numerous.

Left Cervical Gland.—Tubercle bacilli moderately numerous.

Portal Gland (Emulsion).—Tubercle bacilli moderately numerous.

Spleen (Emulsion).—A few tubercle bacilli.

ANIMALS INOCULATED.

With Tissue Emulsion.

Two guinea-pigs inoculated subcutaneously, one from the spleen, the other from a lumbar gland, died of general tuberculosis in 32 and 31 days respectively.

Two rabbits inoculated subcutaneously, one with an emulsion from the spleen, the other with an emulsion from a lumbar gland, died of general tuberculosis in 67 days.

With Culture.

A culture isolated from the spleen of Chimpanzee 16 was used to inoculate a series of rabbits and Chimpanzee 22.

One of the rabbits died prematurely; all the others developed tuberculosis.

CHIMPANZEE 22.

Subcutaneous Inoculation of Culture (5th generation, 21 days old) derived from Chimpanzee 16.

Date—July 4th, 1906.

Dose—0·001 milligramme.

Died—September 29th, 1906.

Duration of Experiment—87 days.

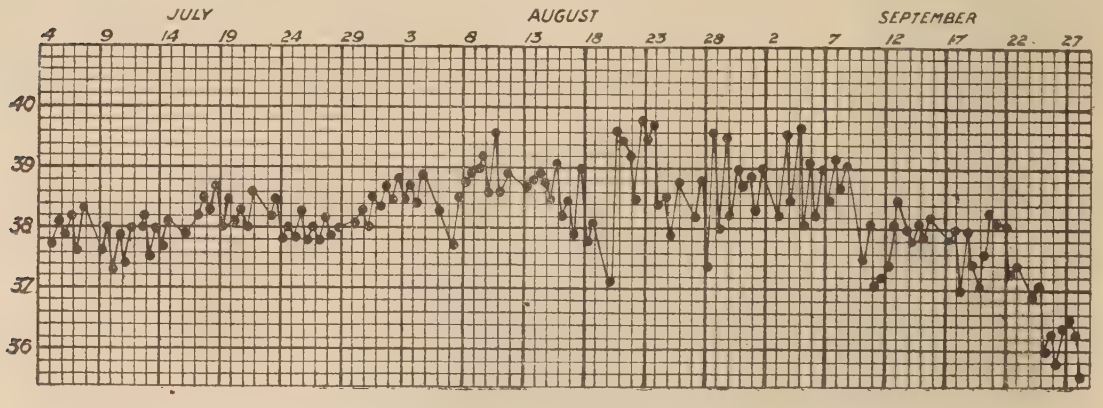
Clinical History.

The chimpanzee was inoculated in the subcutaneous tissue of the back on July 4th, 1906. One month later there was a soft slightly raised tumour about 2 in. in diameter, with a small ulcer in the skin at one margin from an opening in the base of which issued a purulent discharge: the axillary glands were not enlarged. Subsequently the ulcer in the skin became larger and the axillary glands enlarged. The first sign of ill-health appeared six weeks after inoculation and was shown by loss of appetite. From that time it slowly and progressively deteriorated in condition until its death.

Weights.

July 5th, 1906	13 lbs. 9 ozs.
September 29th, 1906	9 lbs. 8 ozs.
Loss in weight	4 lbs. 1 oz.
Average weekly loss	5·41 ozs.

Temperature.



POST-MORTEM EXAMINATION.

Condition.—Body thin; muscles of extremities wasted; very little subcutaneous and abdominal fat.

Local Lesion.—Just to the right of the middle line of the back and lying to some extent on the ala of the right scapula there was a slightly raised tumour measuring 1½ by 1½ by ½ in.; on section the tumour was found to be composed of muscular tissue closely beset with irregular caseous patches and tubercles and to contain near the skin a small compressed cavity lined internally with a thin layer of caseous substance; this cavity had leading from it to the surface a short sinus which opened at the margin of an ulcerated area ¾ in. in greatest diameter. The deeper muscles under the tumour were found to contain caseous tubercles and a soft caseous cord could be traced through an intercostal space into the thorax.

Axillary Glands.—In the right axillary region at about the middle of the margin of the pectoralis major there was a tumour measuring 1½ by 1 by ½ in. composed of several glands which had fused together; on section these glands consisted throughout of yellowish-white breaking down caseous substance; around this mass were numerous small glands, one of which was beset with minute caseous foci. Near the large mass, but lying more under the muscle, were two enlarged glands, each about 1 cm. in diameter, which showed on section yellowish white caseous patches of various sizes, undergoing softening. Near the apex of the axilla were four or five slightly enlarged glands; the largest of these was partly caseous, the others contained discrete caseous foci. The glands in the left axilla were normal with one exception, which contained a soft caseous nodule the size of a hempseed.

Thorax.

On opening the thorax the left lung collapsed and was nowhere adherent to the chest wall; the right lung was universally adherent to the parietal pleura, but could be fairly readily separated from it. The parietal pleura (costal and diaphragmatic) on the right side was thickened, greyish-yellow in colour and roughened on its internal surface.

Lungs.—Both lungs were crepitant; the lobes of the right lung were adherent.

The left lung contained moderately numerous evenly distributed hard grey nodules ranging in size from a pin's head to that of a hempseed; most of the smaller nodules were quite translucent, whilst the larger ones showed a relatively small amount of central caseation; the right lung contained similar but rather less numerous nodules.

Bronchial Glands.—On the right side the prætracheo-bronchial glands (three in number) were fused together to form a mass the size of a thrush's egg; on section they were yellow and caseous throughout and had thick fibrous capsules. On the left side one gland, the size of a sparrow's egg, showed about three-quarters of its substance replaced by soft yellow caseous substance.

The intertracheo-bronchial glands were normal.

The vertebral glands on the right side extending from the fourth to the last dorsal vertebra were enlarged, caseous and softened and embedded in dense white fibrous tissue.

A dorsal mediastinal gland at the level of the fifth vertebra was large, caseous and softened throughout.

A lymphatic gland on the diaphragm near the reflexion of caval fold of pleura contained a soft caseous tubercle.

Diaphragm.—The pleura on the left side of the diaphragm and the peritoneum on the right showed a number of filmy translucent growths varying in size up to about 3 mm.

Heart.—Normal.

Abdomen.

The omentum was devoid of fat and somewhat œdematous; it contained fairly numerous tubercles varying in size from a mere speck up to that of a millet seed.

Spleen.—The spleen was enlarged and measured 4 in. by 2¼ in. by about ½ in. in greatest thickness; on section the pulp contained numerous irregular soft yellow caseous areas ranging from about 2 to 10 mm. in diameter; the larger nodules were composed of firm reddish tissue

(firmer than the surrounding splenic pulp) containing soft yellow caseous areas; two of the smaller nodules projected from the surface and were surrounded by a fringe of congested fibrin.

Splenic Lymphatic Glands.—In the hilum of the spleen there were two enlarged glands, one the size of a broad bean, the other the size of a kidney bean; both on section showed irregular softened caseous areas extensively replacing the gland substance.

Liver.—The liver was paler than normal and showed on the surface about twenty flattened nodules, with overhanging margins, the largest 5 mm. in diameter; on section they were found to extend into the substance and to have yellow caseous centres and grey margins.

Under the capsule and throughout the substance were seen scattered tubercles up to 1 mm. in diameter; some of these were grey with opaque centres, whilst others were homogeneously caseous.

In the small omentum there was a group of four enlarged glands, the largest the size of a broad bean, which on section showed whitish caseous patches extensively replacing the gland substance.

In the hilum of the liver there was a gland, 1 cm. in diameter, similarly affected.

A gland near the neck of the gall-bladder contained a softened miliary caseous tubercle.

Kidneys.—The kidneys were extremely pale. The right showed in the cortex a pinhead-sized caseous focus. In the cortex of the left there were five or six nodules, the largest about 4 mm. in diameter; one of these appeared to be composed of three smaller nodules which had fused together and was completely caseous; the others had grey margins and irregular caseous centres.

Tongue, Pharynx, Tonsils, Larynx and Trachea.—Normal.

Small Intestines.—Three Peyer's patches in the ileum contained each a caseous focus.

Large Intestine.—Normal.

Gastric Glands.—A gland in the lesser curvature of the stomach was beset with soft caseous tubercles.

Mesenteric Glands.—In the anterior part of the mesentery a gland the size of a large pea was irregularly caseated; two smaller glands near the latter were extensively replaced by soft caseous nodules; two other glands in the middle of the mesentery contained each a miliary caseous tubercle.

Ileo-colic Glands.—Normal.

Colic Glands.—Two colic glands were affected; one contained two miliary caseous tubercles, the other contained one.

Lumbar Glands.—One lumbar gland contained a minute caseous focus; the others were normal.

Inguinal and Iliac Glands.—Normal.

Testicles and Brain.—Normal.

Microscopical Examination (Smear Preparations).

Spleen,
Bronchial Gland, } Numerous tubercle bacilli.

Intestines.—A few tubercle bacilli.

CHIMPANZEE PASSAGE.

VIRUS B. IX.

CHIMPANZEE 14.

Fed on September 11th, 1905, with 1·1 mg. of culture derived from the original material of Virus B. IX.

Died—November 13th, 1905. 63 days after.

Post-mortem Examination.

General tuberculosis; intestines and mesenteric glands severely affected.

A culture isolated from an ileo-colic gland was used to feed Chimpanzee 18 and to inoculate subcutaneously a series of rabbits.

One of the rabbits died in 25 days and showed slight tuberculosis; the others died of general tuberculosis in periods varying from 103 to 151 days.

CHIMPANZEE 18.

Fed with culture derived from Chimpanzee **14.**

Date—February 12th, 1906.

Dose—0·01 milligramme.

Weight—11 lbs. 8 ozs.

Died—June 8th, 1906. 116 days later.

Clinical History.

Towards the end of March a mass of enlarged glands was felt on the left side of the neck.

On April 19, 1906, the chimpanzee had a sharp attack of diarrhœa.

Note on April 29, 1906: "For three days has been very weak and apparently unable to walk about the cage; the weakness is manifest chiefly in the legs. The appetite is poor and has not been good for several days. The mass of glands completely fills the anterior triangle and enlarged glands are felt in the posterior triangle as well. The axillary glands are not perceptibly enlarged and no enlarged glands can be felt in the abdomen."

On May 4, 1906, a view was obtained of the left tonsil which was observed to be congested and ulcerated. The skin over the lower part of the mass of enlarged glands was slightly reddened but not adherent. The general condition of the animal was moderate and the appetite was fairly good; the chimpanzee was, however, much quieter and moved very little about the cage. During the rest of the experiment the chimpanzee gradually became more depressed and more and more disinclined to move about; the appetite was capricious but usually a fair quantity of food was taken and there was no apparent bodily wasting. On several mornings there was oedema of the eyelids and of the skin over the lower part of the glandular mass. There was no increase in the rate of respiration during the experiment.

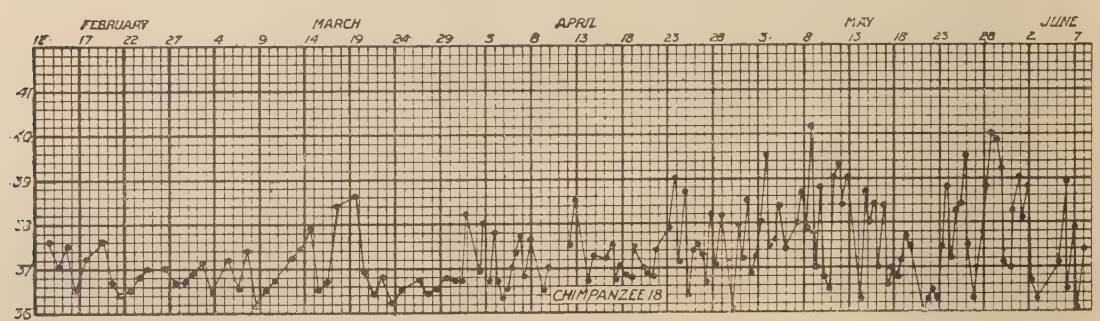
The chimpanzee died rather unexpectedly on June 8, 1906, 116 days after the experiment began.

Weights.

February 21st, 1906	11 lbs. 8 ozs.
March 20th, 1906	12 lbs. 6 ozs.
April 18th, 1906	11 lbs. 2 ozs.
May 15th, 1906	11 lbs. 0 oz.
June 5, 1906	9 lbs. 8 ozs.
June 8, 1906	10 lbs. 4 ozs.
Loss in weight	1 lb. 4 ozs.

Tuberculin Test.—April 10th, 1906. Fifty-seven days after the experiment began. Positive. Rise of temperature 2·3° C. Maximum 40·5° C.

Temperature.



Post-mortem Examination.

Condition.—Arms and legs thin; muscles poorly developed; abdomen full, not distended.

Tonsils.—In the region of the left tonsil there was a deep ulcer with caseo-necrotic walls. The right tonsil was not apparently ulcerated. the surface was irregular and the crypts were filled with whitish purulent material.

Pharynx and tongue appeared normal.

Lymphatic Glands of the Neck.—In the left anterior triangle there was a large mass of enlarged glands extending from the level of the angle of the jaw to the clavicle; in the upper part of the triangle the glands, superior cervical and retropharyngeal, had fused together and formed a soft fluctuating tumour the size of a small orange; over this swelling the sterno-mastoid muscle was stretched; on section the tumour was filled with breaking down caseous material: the glands between this tumour and the clavicle (lower cervical) were enlarged and caseous; around the fluctuating tumour were several isolated enlarged glands; some of these were caseous throughout; others showed caseous patches.

In the left posterior triangle there was a smaller mass of fused glands; on section all were caseous throughout and some were softened.

On the right side in the anterior Triangle there was a mass of glands (superior cervical) measuring $1\frac{1}{4}$ by $\frac{3}{4}$ by $\frac{1}{2}$ in.; on section the glands composing the mass were caseous throughout and beginning to soften. Below this there was a chain of slightly enlarged glands running under the sterno-mastoid; on section these were free from caseation. The retropharyngeal gland was not apparently affected.

Abdomen.

On cutting through the wall of the abdomen the omentum was found to be very intimately adherent to the parietal peritoneum, in several places so firmly that it was impossible to separate them one from the other.

The Peritoneal Cavity.—Contained a small quantity of slightly turbid fluid.

The Omentum.—Was studded with greyish-white somewhat translucent nodules, ranging in size from a mere point to that of a hempseed; some of the larger of these showed minute opaque points in the centre, the others were homogeneous throughout. Along the free margin of the omentum the nodules were aggregated together and formed irregular nodular masses composed of a firm greyish translucent tissue containing sparsely scattered caseous foci.

The Mesentery.—Was covered with similar nodules, the largest the size of a hempseed, here and there aggregated together; a few of the larger ones were definitely caseous in the centre.

There were a few similar tubercles on the serous surfaces of the stomach and small intestine.

On the large intestine there were rather numerous nodules along the line of attachment of the mesocolon; there were numerous nodules also on the mesocolon itself; near the junction of the ileum and cœcum the nodules were closely aggregated together.

All the appendices epiploacæ on the large intestine were devoid of fat and filled with greyish-white miliary tubercles, which in several had fused together to form firm nodular masses of various sizes.

The Parietal Peritoneum.—Was covered with flattened nodules similar in appearance to those on the mesentery; on the anterior abdominal wall they formed an almost continuous greyish-white layer with a yellowish mottling; in the flanks they had united together to form irregular nodular masses similar to those in the omentum; to these masses the large intestine was adherent.

The Peritoneal Surface of the diaphragm showed on the right side irregular plaques of aggregated tubercles, and on the left a uniform greyish-yellow layer of tuberculous tissue; the latter extended over the peritoneum covering the ribs.

Stomach.—Normal.

Small Intestine.—The upper part of the small intestine was normal. Twelve of the Peyer's patches in the ileum showed typical tuberculous ulceration; the ulcers varied from about 5 to 10 mm. in diameter and were mostly circular; the ulcers in the first six patches were caseous chiefly under the margins, two only showing caseous tubercles in their thickened fibroid base; in one of the patches, besides a large ulcer, there were three caseous nodules, the largest of which was ulcerated; on the peritoneal surface of one of the ulcers there were a few raised tubercles; five of the patches in the lower part of the ileum were enlarged, yellow and caseous throughout, and presented nodular elevations on the serous surface; the mucous membrane over some of the patches was almost completely ulcerated, in others only slightly.

The terminal Peyer's patch showed one small ulcer with caseous margins. The large intestine was adherent at several places to the wall of the abdomen; the mucous surface appeared normal.

Gastric Glands.—Præcardiac glands normal.

Duodenal and Pancreatic Glands.—Normal.

Mesenteric Glands.—The glands in the lower part of the mesentery were enlarged and fused together to form a lobulated yellow mass, measuring about 2½ in. by 2½ in by 1 in.; on section the substance of each gland was found to be converted into a soft caseous pulp. In the upper part of the mesentery the glands were normal in size and appearance, with one exception; this was slightly enlarged and showed in the cortex a yellow patch of softening.

In the mesentery near the ileo-cœcal junction there was a small mass of glands, more or less movable on each other; on section some of the glands were caseous and softened practically throughout, whilst the others showed lesser degrees of caseation. Quite near the junction were two isolated glands; one the size of a pea, almost entirely caseous; the other free from caseation.

Colic Glands.—In the mesentery of the ascending colon there was a yellow fluctuating mass, the size of a thrush's egg, around the margins of which were numerous small glands which were normal in appearance; on section the mass was composed of three or four caseous and softened glands which had fused together; near this group there was a pea-sized caseous and softened gland.

On the transverse colon there were two glands close together, the largest the size of a pea; both of these were caseous and softened throughout Other glands along the margin of the colon and the rectal glands appeared normal.

At the root of the meso-colon near the spine there was a group of glands; four of these were about 8 mm. in diameter and showed the substance partly or wholly caseous; two contained each a small nodule; a few others were normal.

Spleen.—The spleen was intimately adherent to the parietal peritoneum and was removed from it only with difficulty; it was much enlarged, measuring 5 by 2½ by about 1 in. in greatest thickness; on its convex surface there was a greyish adherent membrane and two raised firm yellow caseous masses. On section the pulp was closely beset with small irregular soft yellow caseo-purulent nodules, here and there aggregated together to form a larger nodule or a cluster, the individuals forming which were separated by a small amount of splenic tissue.

Splenic Lymphatic Glands.—One the size of a pea was caseous and softened practically throughout; another was partly caseous; others were a little enlarged but were not otherwise abnormal.

Liver.—The capsule of the liver on the right side was intimately adherent to the parietal peritoneum, and on removing the organ was completely stripped from the anterior surface of the right lobe. On the posterior surface of the liver there were numerous flattened slightly raised nodules, the majority not larger than 2 mm. in diameter, which resembled the peritoneal nodules; on the left lobe there were some larger nodules, irregular in outline, ranging up to 1 cm. in diameter; these were greyish-white, and caseous in the centre and penetrated varying distances into the substance of the liver. On the anterior surface the capusle that remained showed numerous small nodules, and one larger more raised and more opaque nodule with a connective tissue outgrowth from its surface; in the substance underneath this there was a soft caseous nodule 4 mm. in diameter.

The liver substance was pale and showed on section sparsely scattered translucent tubercles and a few caseous nodules, some of which were bile-stained. A gland in the hilum of the liver showed two or three tubercles. Two glands in the small omentum were enlarged and contained a few soft yellow nodules.

Kidneys.—The kidneys were very pale; the left showed three translucent nodules, the largest the size of a hemp seed; the latter was slightly opaque and yellowish in the centre.

The right kidney showed three nodules on the surface similar to those in the left and two or three small transparent tubercles; the latter were seen with difficulty on account of the pallor of the tissue surrounding them.

On section one small tubercle was seen in the depth of the left kidney and two or three in that of the right.

Suprarenal Bodies.—Normal.

Thorax.

Each pleural cavity contained a small quantity of clear serous fluid.

Lungs.—The lungs were expanded, congested and œdematous; they contained scattered nodules, ranging in size from a millet seed to that of a pea, evenly distributed throughout the parenchyma; the larger ones were firm yellow and caseous throughout, the smaller ones were grey and translucent or showed minute opaque central foci; there were no areas of consolidation.

Bronchial Glands.—On the left side one in the root of the lung contained a soft caseous tubercle; another near the latter, much enlarged, showed no foci of caseation; other bronchial glands were a little enlarged and firmer than normal, but no foci of caseation were seen.

The Ventral Mediastinal Glands on each side were enlarged, firm and contained each a yellow caseous nodule and several small tubercles.

Dorsal Mediastinal Glands.—Normal.

Pleura.—The parietal pleura on the left side showed one pin-head sized tubercle.

On the pleural surface of the diaphragm there were numerous hard flattened tubercles similar to those on the omentum ; they were most numerous on the left side, the largest being about 2 mm. in diameter. Under the pleura covering the diaphragm were three yellow projecting caseous nodules (? tuberculous glands), the largest the size of a kidney bean.

Near the apex of the heart there was a small gland in a state of early caseation.

Heart.—The pericardial sac was filled with clear serous fluid. The heart muscle and valves were normal.

Inguinal and Axillary Glands.—Normal.

The glands along the abdominal aorta were normal. Under the periosteum about the middle of the parietal suture there was a slightly projecting nodule nearly 1 cm. in diameter ; on section this contained soft caseous material ; the bone beneath it was slightly necrosed.

Brain and Meninges.—Normal.

Microscopical Examination (Smear Preparations).

Right Tonsil.—Numerous tubercle bacilli.

Liver (Nodule in Depth).—A few tubercle bacilli.

Emulsion of Lung.—Numerous tubercle bacilli.

Emulsion of Spleen.—A few tubercle bacilli.

Nodule on Parietal Bone.—Numerous tubercle bacilli.

Animals Inoculated.

A rabbit inoculated intraperitoneally with a small dose of an emulsion made from the lung and killed 76 days later, showed general tuberculosis of the usual type.

A rabbit inoculated intraperitoneally with a small dose of an emulsion made from the spleen and killed 76 days later, showed general tuberculosis, not very severe.

BABOON PASSAGE.

VIRUS B. I.

BABOON 8.

Fed on January 22nd, 1904, with milk of Cow 64 (Table 1A, Volume I.) containing 1,000,000 tubercle bacilli.

Killed.—April 28th, 1904. 97 days later.

Abstract of Post-Mortem Notes.

Ulceration and caseation of both tonsils. Great enlargement and caseation of the pharyngeal, and superficial and deep cervical glands; caseous foci in submaxillary lymphatic glands; one caseous nodule in the right submaxillary salivary gland, and several in the right half of the thyroid. Intestines and mesenteric glands normal. The liver showed several caseating nodules, and a number of miliary tubercles. The spleen contained numerous large softened caseous nodules; the kidneys a few small tubercles. The lungs showed numerous large firm caseous nodules; the bronchial glands caseous foci. There was miliary tuberculosis of the peritoneum, omentum and diaphragm.

A rabbit inoculated intraperitoneally with an emulsion made from a cervical gland was killed, when dying, 88 days after; the post-mortem examination showed general tuberculosis.

A culture was isolated from the cervical gland of Baboon 8 and after cultivation for 533 days was used to feed Baboon 64.

BABOON 64.

Fed with culture from Baboon 8.

Dose.—0·1 milligramme.

Date.—October 13th, 1905.

Died.—January 22nd, 1906. 101 days later.

Clinical History.

The baboon remained lively and well until the end of December. She then became quieter and more irritable and the appetite was not so good. During the first fortnight in January these symptoms became more pronounced and she was obviously losing flesh; the appetite was much diminished.

Towards the end of the experiment she became very emaciated and weak. During the experiment the respirations were never increased and there was no diarrhœa.

Tuberculin Test.—November 24th, 1905, 42 days after feeding. Positive. Rise of temperature 1·7° C.

Post-Mortem Examination.

Body emaciated; no subcutaneous fat.

Both Tonsils were ulcerated and entirely destroyed by caseation; the margins of the ulcers were undermined and the edges congested; the floors were covered with soft caseo-pus, dark coloured on the surface (result of haemorrhage).

Tongue.—Most of the solitary lymphatic follicles at the base of the tongue were caseous and two were ulcerated.

Pharynx.—Normal.

Right Submaxillary Lymphatic Glands.—Normal.

On the right facial vein there were two small caseous tubercles, and on the lower part of the right masseter muscle a caseous gland, the size of a wheat grain.

On the left side there were six enlarged submaxillary glands, the largest the size of a large pea; these on section showed soft caseous nodules, in some replacing almost the whole of the gland substance.

The Left Submaxillary Salivary Gland contained a caseous nodule, about 1·5 mm. in diameter.

The Salivary Gland on the right side was normal.

Retro-Pharyngeal Glands.—Behind each tonsil there was a large irregular mass, the size of a pigeon's egg, consisting of several glands fused together; on section they were all caseous throughout and softened.

Cervical Glands.—In the anterior triangle on the left side and under the insertion of the sterno-mastoid there was a group of enlarged caseous and softened glands; the largest one was the size of a pigeon's egg.

Under the sterno-mastoid in the lower part of the neck there was a chain of enlarged glands, ranging in size from a pea to that of a sparrow's egg; in the posterior triangle under the anterior border of the trapezius there was a gland the size of a sparrow's egg; all these glands were caseous and softened throughout. Two small glands under the middle of the clavicle contained small caseous nodules.

On the right side an upper cervical gland, the size of a French bean, showed caseous areas replacing almost the whole of the substance. A mid cervical gland, slightly enlarged, contained three soft caseous nodules, the largest 3 mm. in diameter. The lower cervical glands on this side were normal.

Abdomen.

The Peritoneal Cavity contained several cubic centimetres of turbid serous fluid.

The Omentum was drawn up and was adherent in several places to the floor of the abdomen and the intestines; it was congested and closely beset with caseous tubercles, the largest 3 mm. in diameter; along the free border the tubercles were closely aggregated together and formed firm masses. The omentum surrounded the spleen which it enclosed in a complete bag; this part of the omentum was also beset with caseous nodules and showed several firm masses composed of aggregated caseous nodules embedded in reddish tissue; the omentum was adherent to the spleen along the hilum and to several projecting caseous nodules.

The Parietal Peritoneum was covered with slightly raised yellowish white caseous tubercles, the largest about 2 mm. in diameter; they were most numerous towards the pelvis and on the diaphragm where they showed a tendency to coalesce.

There were fairly numerous caseous tubercles, up to 2 mm. on the mesentery, and also fairly numerous miliary caseous tubercles on the serous surface of the ileum; on the rest of the intestine they were more sparsely scattered.

Stomach.—Normal.

Small Intestines.—The mucous membrane of the duodenum showed two small ulcers, one with congested margins; in the rest of the intestine there were six typical tuberculous ulcers, majority situated in the ileum; five of these were transverse and ranged from 8 to 10 mm. in length; the margins were thickened and congested and the base contained caseous nodules which projected from the peritoneal surface. The sixth ulcer, situated about three feet from the ileo-cœcal valve, was large and irregular and had congested margins and yellow necrotic base, which was adherent to the peritoneum

over the lumbar vertebrae. The margin of the ileo-coecal valve showed an irregular ulcer with congested margins and caseous base.

Large Intestine.—Normal.

Gastric Glands.—A præcardiac gland contained a small caseous nodule.

Mesenteric Glands.—In the lower part of the mesentery there was an irregular nodular mass of enlarged glands, measuring 1½ by 1½ by nearly 1 in.; on section the glands composing the mass were caseous throughout and had thickened fibrous capsules. The glands in the upper part of the mesentery were not much affected; one was slightly enlarged and caseous throughout; one or two others contained discrete tubercles.

Ileo-Colic Glands.—On one side of the junction of the ileum and coecum there was a group of three glands; two were caseous throughout and fused together; the third was œdematous and deeply congested but free from tubercles. On the opposite side two small glands contained caseous tubercles.

Colic Glands.—Two mid-colic glands lying close together were enlarged to the size of a pea; one was partly caseous, the other was caseous throughout. Other colic glands were normal.

Pancreatic Glands.—Around the head of the pancreas there were several enlarged glands, the largest the size of a sparrow's egg; all were caseous and softened throughout. Along the superior border of the pancreas there were several normal glands.

The Spleen contained two large hydatid cysts; one measured 2½ in. by 2½ in. by 2 in.; the other 1½ in. in greatest diameter; only a small amount of splenic tissue remained; this contained a number of caseous nodules, varying much in size, the largest being about the size of a thrush's egg; the majority were flattened out on the surface of the large cyst from which they projected; on section they were soft, yellow, and caseous throughout. Two splenic lymphatic glands contained caseous tubercles.

The Liver.—Was soft and contained five or six hydatid cysts, the largest the size of a hen's egg; scattered throughout the substance were caseous tubercles, with grey margins, mostly about 1 mm. in diameter; a few were larger and measured 2 mm. in diameter.

The Portal Gland was enlarged and showed more than half the substance caseous.

Kidneys.—The right kidney showed on the surface two caseous miliary tubercles; in the depth of the cortex there was a caseous nodule 3 mm. in diameter. In the cortex of the left kidney there was a caseous nodule, 3 mm. in diameter, projecting from the surface.

Suprarenal Bodies.—Normal.

Thorax.

Heart.—Normal.

Pleura.—On the costal pleura there were a few flattened caseous nodules, each about 2 mm. in diameter.

On the pleural surface of the diaphragm, around the margins of the tendon, there was a number of caseous tubercles in several places arranged in clusters and surrounded by reddish granulation tissue; on the pleura covering the muscle of the diaphragm, chiefly on the left side, there was an eruption of grey granules.

Lungs.—In each of the three lobes of the right lung there was a hydatid cyst; they ranged in size from a pigeon's egg to a hen's egg; in the right cephalic lobe there was a smaller cyst; the lungs also contained fairly numerous firm caseous nodules evenly distributed, ranging in size from about 2 up to 8 mm. in diameter; the nodules were caseous throughout with the exception of a narrow grey or greyish red margin.

Bronchial Glands.—A superior bronchial gland on the right side contained two caseous foci. Other bronchial glands appeared normal. The ventral mediastinal glands were enlarged and closely beset with discrete caseous tubercles.

Special Lymphatic Glands.

Axillary and Inguinal Glands.—Normal.

Lumbar Glands.—Two, the size of sparrows' eggs, were caseous throughout; several others contained discrete caseous tubercles.

Iliac Gland.—Normal.

Uterus.—Normal.

Brain and Meninges.—Normal.

Microscopical Examination (Smear Preparations).

Cervical Gland, Lung. } A few tubercle bacilli.

Guinea-pig Inoculated.

A guinea-pig inoculated with an emulsion made from the lung died 8 days afterwards, too soon for tuberculosis to have developed.

BABOON PASSAGE.

VIRUS B. IV.

BABOON 22.

Fed for 25 days with tuberculous milk of Cow 172 (Table IVa, Volume I) from September 9th, 1904, until October 4th, 1904.

Died.—December 8th, 1904. 90 days after the experiment began.

Abstract of Post-Mortem Notes.

Both tonsils were enlarged but not ulcerated; the right showed in the centre a soft caseous mass; the left two caseous foci; the lymphoid follicles at the base of the tongue were enlarged, caseous, and ulcerated. The mucous membrane of the stomach showed six small tuberculous ulcers. The small intestine was severely affected; the upper half was covered with typical tuberculous ulcers with sub-peritoneal tubercles; the lower half was affected chiefly in the last 12 inches, where there were several groups of ulcers in the Peyer's patches. In the first part of the large intestine there were six ulcerated caseous nodules. Pharyngeal, superior cervical, ileo-colic, several colic, and the lumbar glands were greatly enlarged and caseous throughout. The mesenteric glands formed a very large irregularly softened caseous mass adherent in its upper part to the duodenum into which it had ulcerated. The mesentery corresponding to the upper half of the intestine was greatly thickened and tuberculous. Omentum and peritoneum studded with tubercles. Lungs crammed with caseous nodules, the largest the size of a large marble. Bronchial glands only slightly affected. The spleen contained numerous large softened caseous nodules; the liver caseous nodules up to the size of a pea and innumerable minute grey foci. The left kidney contained two caseous nodules, the right one. Diaphragm covered with tuberculous growths chiefly on the right side. One ileo-sacral, two splenic, and two left submaxillary glands contained caseous tubercles; the portal glands were beset with caseous nodules.

Animals Inoculated.

A culture was isolated from a cervical gland and, when it had been in cultivation 292 days, used to inoculate three rabbits and to feed Baboon 62.

No. of Rabbit.	Initial Weight in grammes.	Final Weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	RESULT.
481	1,330	1,020	1·0 mg.	Intraperitoneal	Died 25 days	General tuberculosis of the usual acute type.
482	1,280	1,070	0·1 mg.	Intraperitoneal	32 days (killed accidentally)	General tuberculosis, almost as severe as in Rabbit 481.
480	1,200	1,050	0·01 mg.	Intraperitoneal	Died 37 days	General tuberculosis; lungs packed with caseous coalescing tubercles. Tubercles not so numerous on the peritoneum as in the first two cases.

BABOON 62. (Adult Male).

Fed with culture from Baboon 22.

Dose.—0·1 milligramme.

Date.—September 26th, 1905.

Died.—February 9th, 1906. 136 days after feeding.

Clinical History.

During the first seven weeks his condition was unchanged. About the middle of November he was quieter and more tractable, and towards the end of November he began to have difficulty in breathing, especially after food, due, apparently, to enlargement of the retro-pharyngeal glands.

He then (from about the middle of December) began gradually to lose flesh and strength; the appetite, however, remained undiminished.

The glands in the neck became more and more enlarged and caused greater and greater difficulty in breathing; ordinary quiet respiration was accompanied by a snoring noise, which was very pronounced during sleep and when drinking.

At the end of January he was very thin and weak and moved very little about his cage.

On the day preceding his death there was a hæmorrhagic discharge from the nostrils.

During the experiment there was no increase in the rate of respiration, and no diarrhœa.

At the beginning of the experiment an attempt was made to get a record of the temperature, but was discontinued on account of the animal's uncontrollable struggles.

Post-Mortem Examination.

Tongue.—Normal.

Both Tonsils were slightly enlarged and composed of firm greyish red tissue, containing irregular patches of caseation; there was no ulceration.

Submaxillary Glands.—On the right side three, anterior to the salivary gland, were slightly enlarged and contained from one to three soft caseous nodules, the largest about 3 mm. in diameter. In a gland near the angle of the jaw there were four miliary caseous tubercles. On the left side one gland contained a pea-sized softened caseous nodule.

Submaxillary Salivary Glands.—Normal.

Retro-Pharyngeal Glands.—The pharyngeal glands were very greatly enlarged, and formed on each side a large irregular mass extending from the base of the skull to the level of the larynx. The naso-pharynx was almost completely filled in. The two masses had united in the midline in the upper part; the wall of the pharynx here showed a deep necrotic ulcer from which recent hæmorrhage appeared to have taken place. On section the glands on each side were fused together and were caseous and softened throughout.

Cervical Glands.—On the left side in the middle of the neck there was a large soft mass measuring $1\frac{3}{4}$ in. by $\frac{3}{4}$ in. by about $\frac{2}{3}$ in., which on section was found to be composed of several glands fused together; these were all completely caseous and softened. Internal to the carotid artery on the level of the larynx there was a gland the size of a pigeon's egg, which on section was a thin-walled cyst filled with caseo-pus (immediately above this gland were the enlarged pharyngeal glands); between this and the clavicle along the carotid artery there was a chain of small glands which were normal in appearance. Behind the left clavicle there were three small glands beset with soft caseous tubercles and a gland

the size of a broad bean, composed of greyish-red translucent tissue closely studded with soft caseous tubercles, up to 1·5 mm. in diameter.

In the middle of the neck on the right side external to the carotid artery there was a large soft gland measuring 1¾ in. by 1 in. by 1 in. which on section was filled with caseo-necrotic masses and caseo-pus; internal to the carotid artery there was a gland the size of a sparrow's egg, which was caseous and softened practically throughout (immediately above this were the enlarged pharyngeal glands).

Behind the outer extremity of the clavicle on the right side there were two glands, each 1 cm. in greatest diameter, filled with caseous and softened nodules which almost completely replaced the gland substance.

Abdomen.

The Peritoneal Cavity contained a small amount of blood-stained fluid.

The Omentum was very closely studded with yellow, caseous, and softened nodules ranging in size from a No. 4 shot to a barley grain; in many parts of the omentum the nodules were closely aggregated together; the lower part of the omentum showed a large irregular mass, composed of reddish fibroid tissue, closely beset with caseous softening nodules up to 2 mm. in diameter.

On the meso-colon and serous surface of large intestine there were fairly numerous caseous nodules, similar to those in the omentum. There were similar but less numerous nodules on the mesentery; these stood up prominently above the surface, and in many places occurred in small clusters.

The Parietal Peritoneum showed chiefly on the right side and on the diaphragm fairly numerous somewhat flattened caseous nodules; on the left side and in the right lumbar region there was besides an eruption of minute transparent granules.

Stomach.—The mucous membrane showed numerous punctiform hæmorrhages; otherwise normal.

Small Intestine.—In the early part of the ileum there was a small transverse healing ulcer with congested margins; in the base there were about half a dozen caseous tubercles which projected from the serous surface. In another part of the ileum there was a caseous tubercle about 1·5 mm. in diameter, which projected beyond both surfaces: the mucous membrane was not ulcerated.

Large Intestine.—Except where it was adherent to the ileo-colic glands, was normal.

Gastric Glands.—A gland in the lesser curvature of the stomach was enlarged, and contained three soft, yellowish, caseous nodules, up to 3 mm.

Duodenal Glands.—On the first part of the duodenum above the head of the pancreas there were several glands; one contained a caseous tubercle; the others were normal. Below the head of the pancreas there was a group of enlarged glands, all of which were caseous and softened throughout.

Mesenteric Glands.—The mesenteric glands were enlarged and fused together to form a smooth fluctuating tumour 2 in. by 2 in. by 1½ in.; on the surface a few caseous nodules projected from under the peritoneum; on section the tumour was a very thin-walled cyst filled with caseo-pus.

Ileo-Colic Glands.—The glands on one side of the junction of the ileum and the cœcum formed a large, irregular, caseous and softened mass which was adherent to the cœcum in two places: at one of these places the mass had ulcerated into the lumen of the gut, the mucous membrane showing three separate openings through which caseo-pus could be expressed.

On the opposite side of the junction there were two slightly enlarged glands which contained a few soft caseous nodules.

Colic Glands.—Three showed soft caseous nodules in the cortex; a few others showed one or two early tubercles.

The Spleen was enlarged and measured 3½ in. by 1½ in. by 1; on the surface there were a few flattened caseous nodules; the pulp contained very numerous thin-walled nodules filled with yellow tenacious pus (mucoid in character); they ranged in size from a shot to a large pea.

In the hilum of the spleen there was a caseous and softened gland, the size of a French bean.

Liver.—On the surface under the capsule there was a moderate number of caseous nodules, with fibrous margins, ranging from 1 to 2 mm. in diameter: in the depth no large nodules were seen, but extremely minute grey tubercles just visible to the eye and a few miliary tubercles with slightly opaque centres.

The Portal Gland was enlarged and contained in the cortex two or three soft caseous nodules.

The Left Kidney showed in the cortex three caseous nodules, 1·5 to 3 mm. in diameter.

The Right Kidney contained one soft caseous nodule 2·5 mm. in diameter.

Suprarenal Bodies.—Normal.

Thorax.

Heart.—The pericardium was universally adherent to the heart, the pericardial sac being obliterated; the heart muscle and valves were normal.

Lungs.—The left lung showed numerous thin fibrous adhesions to the costal pleura and diaphragm; the two lobes were intimately adherent.

The right lung was firmly adherent to the diaphragm and showed more recent adhesions to the ribs.

The right upper and lower lobes were crepitant, except for a patch of red hepatisation in the latter, and contained numerous caseous nodules with narrow grey margins, ranging from 1 to 3 mm. in diameter; in the upper lobe there was besides a caseous nodule 1 cm. in greatest diameter. The right middle lobe was completely consolidated and externally had a dark red colour; on section it was beset with caseous nodules, which near the root of the lobe were closely aggregated together and much softened.

The left lobes contained numerous caseous nodules similar to those in the right; there were besides four larger nodules, one measuring 1·5 cm in greatest diameter.

Pleura.—There were no tubercles on the pleura.

Bronchial Glands.—The prætracheo-bronchial glands were enlarged and contained discrete caseous nodules up to 2 mm. in diameter; one intertrachea-bronchial gland on the right side was much enlarged, œdematous and congested, and contained similar nodules.

Dorsal Mediastinal Glands.—Normal.

Ventral Mediastinal Glands.—Enlarged and very closely beset with discrete soft caseous nodules ranging up to 2 mm. in diameter.

Larynx and Trachea.—Normal.

Special Lymphatic Glands.

Cœliac Glands.—One the size of a swallow's egg, was caseous and softened throughout.

The Lumbar and Iliac Glands were enlarged and contained numerous soft yellow caseous nodules, up to 2·5 mm. in diameter (one right iliac gland was normal).

Inguinal and Axillary Glands.—Normal.

Special Organs.

Testicles.—Normal; on the tunica vaginalis were several small hard tubercles.

Brain and meninges.—Normal.

Under the periosteum of one of the frontal bones there was a slightly raised red gelatinous nodule, about 1 cm. in diameter, containing soft yellow foci; this nodule lay in a shallow carious depression in the bone.

Microscopical Examination (Smear Preparations).

Left Tonsil.—Fairly numerous T.B.

Spleen (emulsion).—A few T.B.

Lung (emulsion).—A few T.B.

Nodule under Periosteum of Frontal Bone.—Numerous T.B.

Guinea-pigs Inoculated.

No. 1899, inoculated intraperitoneally with an emulsion made from a lung nodule, died 43 days later of general tuberculosis.

No. 1900, inoculated intraperitoneally with an emulsion made from the spleen, was killed with 1·0 cc. tuberculin and found to have general tuberculosis.

RHESUS MONKEY AND BABOON PASSAGE.

VIRUS B. I.

MONKEY 76.

Fed on April 7th, 1904, with 0·01 mg. of culture obtained from a supramammary lymphatic gland of Cow 44. *see* Vol. I.

Killed when dying, November 21st, 1905. 228 days after.

Abstract of Post-mortem Notes.

Tonsils and pharynx, normal. Twelve to fifteen small caseous ulcers in small intestine. Enlargement, caseation and softening of the pharyngeal, abdominal and thoracic lymphatic glands. Liver beset with miliary tubercles and softened nodules. Spleen, adherent, greatly enlarged and extensively caseated. Each kidney contained moderately numerous tubercles. The lungs showed numerous miliary tubercles and several large consolidated areas, some far advanced in caseation; in one of the latter there was an irregular cavity. There was tuberculosis of the omentum, peritoneum, pleura and pericardium.

A culture was isolated from the spleen and used to inoculate a series of six rabbits and to feed Baboon 66.

All the rabbits died of general tuberculosis.

BABOON 66.

Fed with culture from Monkey 76.

Dose.—0·1 milligramme.

Date.—September 27th, 1905.

Died.—February 7th, 1906. 133 days after.

Clinical History.

There was no disturbance in the general health until about the middle of January. He was then noticed to be becoming quieter and to be less inclined for food; he also seemed to be losing flesh. He rather quickly became weaker and thinner and died about 17 days after he was first observed to be ill. There was no increase in the respiration, and no diarrhœa during the experiment.

Tuberculin Test.—November 24th, 1905, 58 days after the experiment began. Doubtful. The temperature rose to 39·4° C. (maximum before the inoculation of the tuberculin 38·8 C.) 5 hours after inoculation, and then fell to 38·1° C. at the 12th hour; it gradually rose again and reached 40·7° C. at the 27th hour.

Temperature.—The temperature remained practically normal (maximum 39·2° C.) until January 19th; it then gradually fell to a lower and lower level, and finally no temperature could be recorded with the clinical thermometer.

Post-Mortem.

Body.—Slightly emaciated.

Tongue and Tonsils.—Normal.

Pharynx.—The mucous membrane of the vault of the pharynx showed an oval ulcer, 1 cm. in length, with inverted edges, smooth, undermined margins and congested, uneven floor; the base was fibroid and contained yellow caseous tubercles.

Submaxillary Glands.—Normal.

Retro-Pharyngeal Glands.—On the right side there was a group of three glands, the largest the size of a swallow's egg; these were firm and practically caseous throughout.

On the left side there were four glands, the largest the size of a large pea; two of these were caseous throughout; the third was partly caseous; the fourth contained discrete caseous nodules, irregular in outline.

Cervical Glands.—On the right side in the middle of the neck there was a gland the size of a broad bean which was firm and practically caseous throughout (composed of closely aggregated tubercles); below this there was a gland the size of a French bean closely beset with firm caseous nodules; between the carotid artery and the larynx there were three small glands which were caseous throughout; two small glands under the right clavicle contained caseous tubercles.

On the left side the cervical glands were normal.

Abdomen.

The Omentum was closely studded with caseous nodules with grey margins, ranging in size from a millet seed to that of a wheat grain; they remained discrete except near the spleen, where they were aggregated together into two or three small groups.

The Parietal Peritoneum near the spleen was studded with flattened caseating tubercles up to 1 mm.; there were similar caseous tubercles on the peritoneum covering the diaphragm, and near the spleen a yellow caseous patch about 1 mm. thick; below the spleen the peritoneum was covered with small pearly grey tubercles; on the right side the tubercles were sparsely scattered.

On the mesentery and serous surface of stomach there were a few nodules similar to those in the omentum.

Stomach.—Mucous membrane normal.

Small Intestine.—About 12 inches from the pylorus there was a small circular ulcer with irregular, slightly thickened margins and thin fibroid base in which one or two yellow points were seen. In a Peyer's patch 15 inches from the ileo-coecal valve there was an oval transverse ulcer 1 cm. in greatest diameter with thick raised irregular margins and caseous base; the peritoneum over them was thickened and darkly pigmented; there were no sub-peritoneal tubercles.

Large Intestine.—Normal.

Mesenteric Glands.—In the upper part of the mesentery there was a large gland, 1 in. in greatest diameter; on section it was caseous throughout and softened in the centre. In the lower part of the mesentery there was a group of three glands, the largest $\frac{2}{3}$ in. in diameter; these were also caseous throughout, but not softened. Most of the glands in the middle of the mesentery were normal; some contained small caseous tubercles or small nodules.

The Ileo-Colic Glands.—Were normal with one exception, which contained a small caseous focus.

Colic Glands.—One contained an irregular caseous nodule about 2 mm. in diameter; the rest were normal.

The Spleen.—Was somewhat enlarged and contained about 15 spherical nodules, some of which projected from the surface, majority about 1·5 cm. in diameter; the nodules were yellow and caseous throughout and softened in the centre.

Splenic Lymphatic Glands.—In the hilum of the spleen several lymphatic glands were enlarged and contained discrete caseous tubercles embedded in firm grey tissue.

The Liver.—Was normal in general appearance and showed scattered throughout the substance moderately numerous caseous tubercles ranging in size from 0·5 to 2 mm. in diameter.

The Portal Gland.—Contained three or four caseous tubercles in the cortex.

Kidneys.—Normal.

Suprarenal Bodies.—Normal.

Thorax.

Heart.—Normal.

Pleura.—Costal pleura normal; on the tendon of the diaphragm on the left side there was a yellow granular

patch composed of closely aggregated tubercles; elsewhere the diaphragmatic pleura showed scattered caseous tubercles.

The Lungs.—Collapsed normally, and were crepitant throughout. The left lower lobe was adherent to the patch on the diaphragm, the visceral pleura at this point being opaque and thickened.

In the right upper lobe there was one opaque miliary tubercle; in the right middle lobe there were two caseating tubercles, 1 and 2 mm. in diameter respectively; in the right lower lobe there were about half-a-dozen caseous tubercles with grey margins, ranging from 1 to 2·5 mm. in diameter.

The left lobes contained each about nine miliary caseous tubercles.

Bronchial Glands.—One left prætracheo-bronchial gland contained a firm caseous nodule 5 mm. in diameter; another contained a smaller caseous nodule. A right prætracheo-bronchial gland contained a small caseous tubercle. An intertracheo-bronchial gland on the right side showed one caseous tubercle and two on the left side small caseous nodules.

The Dorsal Mediastinal Glands.—Five in number, were enlarged, firm, and caseous throughout.

The Ventral Mediastinal Glands.—Contained a few discrete tubercles.

Lumbar Glands.—Slightly enlarged, showed on section firm caseous tubercles, varying in size.

Iliac Glands.—One on the left side, the size of a pea, was caseous throughout; those on the right side were normal.

Inguinal and Axillary Glands.—Normal.

Brain and Meninges.—Normal.

Testicles.—Normal.

Microscopical Examination (Smear preparations).

Spleen	- - - -	2 tubercle bacilli seen.
Cervical Gland	- -	4 tubercle bacilli seen.

RHESUS MONKEY PASSAGE.

VIRUS B. IX.

MONKEY 110.

Fed on June 2nd, 1905, with 1·0 mg. of culture derived from the original material of Virus B. IX.

Killed, when dying, September 28th, 1905. 80 days later.

Abstract of Post-Mortem.

Tonsils and glands in neck normal. The stomach showed one small ulcer; the small intestine, 10 typical tuberculous ulcers, the largest 10 × 4 mm.; there were two submucous caseous nodules in the large intestine. The mesenteric glands were caseous throughout, and formed a large fluctuating mass. Almost all the other abdominal lymphatic glands were enlarged and caseous. The spleen contained 7 or 8 caseous nodules, the largest the size of a pea; the liver showed about two dozen caseous tubercles on the surface and there were fairly numerous caseous tubercles in each kidney. The lungs were closely beset with miliary caseous tubercles, and the bronchial glands were caseous. There were two tubercles in the right suprarenal body, two on the omentum, one in the pancreas, and one on the parietal pleura. The cortex of the brain showed about half a dozen caseous nodules.

Animals Inoculated.

A culture was isolated from an iliac gland, and when it had been in cultivation 55 days was inoculated intraperitoneally into two rabbits and subcutaneously into two rhesus monkeys, Nos. 114 and 116. Both rabbits died of general tuberculosis in 22 and 37 days respectively.

RHESUS MONKEY 114.

Subcutaneous.—Inoculation of culture from Monkey 110.

Dose.—0·01 milligramme.

Date.—November 22nd, 1905.

Died.—December 25th, 1905. 33 days after inoculation.

Clinical History.

The monkey was inoculated subcutaneously between the shoulders on November 22, 1905.

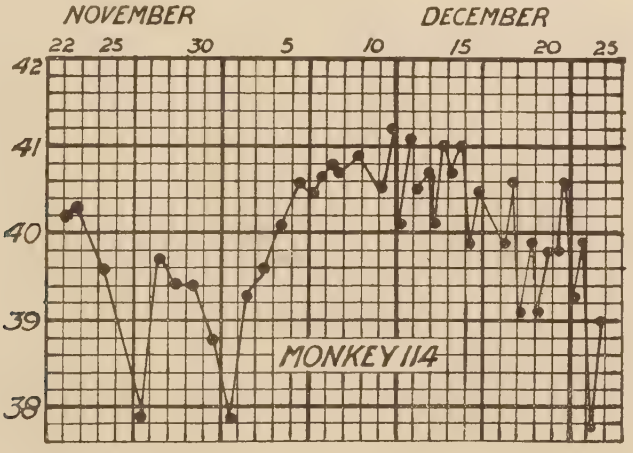
Fifteen days after inoculation there was a rounded swelling, about 1½ in. in diameter, soft and fluctuating in the centre; there was a small opening in the skin. Six days later the swelling was larger and there were three openings in the skin through which yellow pus was discharged.

On December 15 the skin showed an ulcer ½ in. in diameter covered by a scab; removal of this and pressure on the tumour caused thick brownish yellow pus to exude; there were also two small openings covered by scabs. The ulcers enlarged and coalesced and the tumour became much collapsed and appeared to have increased in area.

The axillary glands on both sides became moderately enlarged.

At the end of the third week the monkey was noticed to be unwell; he was thinner and appeared to be losing appetite. The general condition gradually became poorer, and although the appetite was moderate he was obviously losing flesh. On December 23rd he became much worse, and was found dead on the 25th.

Temperature



Post-mortem.

Body.—In poor condition.

Local Lesion.—At the site of inoculation in the middle line of the back, just below the inferior angle of the scapula, there was a slightly irregular oval ulcer, 1 in. × ¾ in.; the margins were thin, reddened, undermined, and partly caseous. The ulcer led into a cavity 2 in. in diameter filled with soft caseous substance; the walls were formed by the muscles of the back, which were infiltrated by caseation.

The Right Axillary Gland.—½ in. long, had the cortex caseous and contained discrete tubercles in the medulla. The gland on the left side was similar.

Thorax.

Parietal Pleura.—Normal.

The right pleural cavity contained an excess of fluid.

Lungs.—The right lung was dark and congested and contained a moderate number of discrete tubercles up to 2·5 mm. in diameter. The largest were caseous with translucent grey margins. On the dorsal surface of the lung there was a fibrinous deposit.

The left lung was pink in colour and contained fewer tubercles up to 2 mm.: they were grey and translucent with opaque centres.

Bronchial Glands.—The right bronchial gland was enlarged and contained soft yellow caseous tubercles up to

1·5 mm.; they were numerous and were arranged round the cortex. The left bronchial gland was small and contained three caseous tubercles. Each prætracheo-bronchial gland contained a single miliary tubercle.

Heart.—In the muscle of the right ventricle there was one pinhead-sized tubercle, and one twice the size in the left. Cavities of the heart normal.

In the dorsal mediastinum on each side of the spine there was a chain of soft caseous lymphatic glands the largest the size of a kidney bean.

Abdomen.

Peritoneum and Omentum.—Normal.

The Spleen was greatly enlarged, measuring 3 in. $1\frac{3}{4}$ in. × $\frac{3}{4}$ in.; it contained numerous tubercles, varying in size from minute grey points up to 3 mm. in diameter. The largest were irregular in outline, opaque and caseous throughout. In the splenic lymphatic gland there were a few discrete tubercles.

The Liver was large and was closely beset with tubercles the smallest minute and grey, the largest up to a pinhead in size, yellowish and caseous.

The Portal Gland was enlarged and the cortex was filled with yellowish tubercles larger than a pinhead.

Kidneys.—In each kidney there were about six scattered grey tubercles with minute opaque centres: on section there were scattered tubercles in the depth. In the right kidney in addition there was a pin head sized yellow tubercle.

Suprarenal Bodies.—In the right suprarenal there was one opaque miliary tubercle.

Lymphatic Glands.

The Mesenteric Glands were not enlarged and in each of these there was a minute opaque tubercle.

In the *Submaxillary, Inguinal, and Left Iliac Glands* there were from one to three pinhead sized caseous tubercles.

Lumbar Glands.—Normal.

Microscopic Examination (Smear Preparation).

Inguinal Gland.—Numerous tubercle bacilli.

Animals Inoculated.

A culture was recovered from an axillary gland and, when it had been in cultivation 27 days, was inoculated subcutaneously into three rabbits and used to feed two monkeys, Nos. 130 and 132.

All the rabbits died of general tuberculosis.

RHESUS MONKEY 116.

Subcutaneous.—Inoculation of culture from Monkey 110.

Dose.—0·01 milligramme.

Date.—November 22nd, 1905.

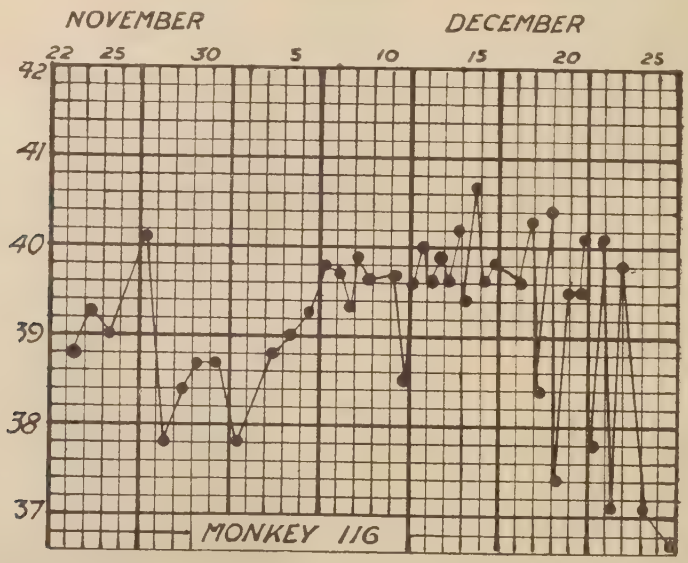
Died.—December 28th, 1905. 36 days after inoculation.

Clinical History.

The monkey was inoculated subcutaneously between the shoulders.

A fortnight after inoculation there was a slightly raised soft swelling measuring nearly 1in. in diameter; on the 23rd day the swelling measured $1\frac{3}{4}$ in. by $1\frac{1}{4}$ in. and subsequently there was a little further increase in size. A fortnight after inoculation the axillary glands were felt to be slightly enlarged; during the rest of the experiment they underwent little further enlargement. Up to December 22 there was no change in the general condition, except that latterly the animal was quieter; then illness (rough coat, depression and anorexia,) rapidly supervened and the animal soon became collapsed and died.

Temperature.



Post-mortem.

Body emaciated.

Local Lesion.—At the site of inoculation, in the mid line of the back, there was a soft fluctuating tumour ($2\frac{1}{2}$ in. by $1\frac{1}{4}$ in.) situated between the skin and muscle. On section it showed a fibro-caseous wall filled with yellow caseo-pus.

The Axillary Glands on both sides were enlarged and contained nodules filled with soft caseo-pus.

Cervical Glands.—The right inferior cervical gland was enlarged and contained pinhead yellow tubercles: the left was small and appeared normal.

Abdomen.

The Spleen, little if at all enlarged ($1\frac{1}{2}$ in. by $\frac{3}{4}$ in. by $\frac{1}{2}$ in) contained numerous tubercles varying in size, the smallest minute and grey, the largest up to 3 mm. in diameter, with soft yellow caseous centres. Those under the capsule projected slightly.

Liver.—The liver contained numerous minute grey foci just visible and a moderate number of large tubercles varying in diameter up to 3 mm. The largest of these had thin fibrous capsules and were completely softened in the centre.

The Portal Gland was a little enlarged and contained a soft yellow nodule.

The Kidneys and *Suprarenal Capsules* appeared normal.

Thorax.

Heart.—Normal.

Pleura.—The right pleural cavity contained a little fluid, and the right lung was more collapsed than the left. On the left side under the pleura at the junction of the eighth rib with the spine was a pea-sized softened yellow nodule.

Lungs.—In the lungs were sparsely scattered grey translucent tubercles up to 2 mm. in diameter, the largest of which showed minute soft yellow centres.

Bronchial Glands.—The bronchial glands were normal.

Various Lymphatic Glands.

Lumbar and Iliac Glands.—Normal.

Sternal glands were a little enlarged and contained pinhead sized caseous tubercles.

There was a pinhead sized caseous tubercle in each sub-maxillary gland, and in each of two mesenteric glands and in a left inguinal gland. Right inguinal glands normal.

Microscopical Examination.

Axillary gland showed a moderate number of T.B.

RHESUS MONKEY 130.

Fed with culture obtained from an axillary gland of Monkey 116.

Dose—0·01 milligramme.

Date—January 24th, 1906.

Killed, when dying, April 20th, 1906. 86 days after being fed.

Clinical History.

Signs of ill-health, rough coat and depression were first noticed on March 31st, 1906.

On April 16th the monkey was obviously ill and appeared to be losing flesh; there was occasional cough but no increase in respiration.

The animal rapidly became worse and lost appetite; it was killed in a dying condition on April 20th, 1906. 86 days after the experiment began.

Tuberculin Test.—April 10th, 1906. 76 days after the experiment began. Positive. Rise of temperature 1·1° C.

Temperature.

The temperature was slightly raised from February 21st to February 26th, maximum 39·7° C.; and again from March 29th until the end of the experiment, maximum 40°C.

Post-mortem Examination.

Body.—Condition, moderate.

Tongue, Tonsils and Pharynx.—Normal.

Submaxillary, Retro-Pharyngeal and Cervical Glands.—Normal.

Abdomen.

Omentum and Peritoneum.—Normal.

Stomach.—Normal.

Small Intestine.—Normal.

Large Intestine.—Normal.

Mesenteric and Colic Glands.—Normal.

One Ileo-colic Gland contained a grey miliary tubercle, with a caseous centre.

A Cœliac Gland contained a similar tubercle.

A Gland on the head of the pancreas contained two miliary caseating tubercles.

The Spleen was enlarged and showed on the surface numerous projecting yellow nodules, the largest about 8 mm. in diameter; the nodules were thin-walled and filled with caseo-pus; on section similar nodules were seen in the interior of the spleen.

Splenic Lymphatic Glands.—Normal.

The Liver was normal in general appearance; in the substance just under the capsule, there were three or four tubercles, the largest about 1 mm. in diameter with caseous centres and grey margins. On section two or three small tubercles were seen in the depth.

The Portal Gland appeared normal.

The Left Kidney showed in the cortex a grey tubercle with a slightly opaque centre. In the right kidney there was a grey miliary tubercle with no central opacity.

Suprarenal Bodies.—Normal.

Thorax.

Heart.—The pericardial sac contained a small quantity of clear serous fluid; heart muscle normal.

Lungs.—The right middle lobe and an accessory right middle lobe were much enlarged and filled the lower part of the right pleural cavity; the former was firmly adherent to the chest wall in front and laterally and less firmly to the upper and lower lobes; on section the middle lobe was composed partly of grey translucent tissue, closely beset with irregular caseous patches and tubercles, and partly of firm yellow caseated tissue, showing here and there small islands of grey translucent tissue; the accessory middle lobe was almost uniformly yellow and caseous; there was no sign of softening.

The right lower lobe was crepitant in the dorsal part and consolidated near the root; the solid portions were composed of firm translucent grey tissue in a less advanced stage of caseation than the middle lobes; the crepitant part contained a few discrete caseating nodules.

The right upper lobe contained about eight nodules, similar to those in the left lobes, and a small patch composed of grey caseating tubercles closely aggregated together.

The left lobes were dark red, collapsed and quite airless; they contained altogether about two dozen nodules, ranging in size from a pin's head to that of a pea; on section the nodules were firm yellow and caseous in the centre, grey and translucent around the margins.

Bronchial Glands.—On the left side two prætracheo-bronchial glands were affected; one contained a caseous nodule, 2 mm. in diameter; another a small caseous tubercle; one intertracheo-bronchial gland on this side contained a miliary caseous tubercle.

On the right side the glands were moderately enlarged; two prætracheo-bronchial glands were beset with caseous tubercles, here and there becoming confluent; one intertracheo-bronchial gland, the size of a broad bean, was composed of irregular yellow caseous areas, some softened, separated by a small amount of translucent grey tissue.

Ventral Mediastinal Glands.—One on the right side, the size of a French bean, was beset with discrete caseous tubercles, irregular in outline, ranging from a mere point to 1·5 mm. in diameter; another contained a miliary caseous tubercle; the rest were normal.

Vertebral Glands.—The glands in the intercostal spaces near the vertebral column were on the right side all enlarged; one in the third space showed three caseating tubercles and one in the ninth one minute tubercle; in the rest there were no opaque foci. On the left side the glands were normal.

Parietal Pleura.—The pleura, where it was adherent to the right middle lobe, was roughened and shaggy and showed two loosely attached caseous nodules, the largest 3 mm. in diameter; there were two similar nodules in the upper part of the chest and about half-a-dozen miliary caseating tubercles.

Lumbar and Iliac Glands.—Normal.

Inguinal and Axillary Glands.—Normal.

Brain and Meninges.—Normal.

RHESUS MONKEY 132.

Fed with culture obtained from an axillary gland of Monkey 116.

Date—January 24th, 1906.

Dose—0·0001 milligramme.

Died—June 7th, 1906. 134 days after the experiment began.

Clinical History.

The monkey showed no obvious signs of ill-health until about the middle of May; the coat was then noticed to be rough and he appeared to be losing flesh; he gradually became perceptibly thinner and lost appetite and was found dead on June 7, 1906, 134 days after the experiment began; the respirations were not noticeably increased and there was no diarrhœa.

Tuberculin Test.—10th April, 1906, 76 days after the experiment began. Positive. Rise of temperature, 1·2°C. Dose of tuberculin 2·0 cubic centimetres.

Temperature.—The temperature from the beginning of the experiment until 19th April, was normal, with exception of a slight rise, to 39·8° C. on 3rd April, 1906. From April 16th to May 10th there was a period of slight pyrexia (maximum, 39·0° C.); then after a slight fall the temperature rose, and from May 15th to May 25th was sustained at a fairly high level (maximum 40·8° C.); subsequently it assumed a lower level, falling finally below 37° C.

Post-mortem Examination.

Tongue, Tonsils and Pharynx.—Normal.

Submental, Submaxillary, Retropharyngeal and Cervical Glands.—Normal.

Abdomen.

The Omentum contained a few small transparent bodies which were probably early tubercles.

Stomach and Intestines.—Normal.

Gastric Glands.—A gland in the lesser curvature of the stomach near the pylorus contained a pin-head sized caseous tubercle.

Mesenteric Glands.—One mesenteric gland, the size of a large pea, was filled with yellow tenacious caseo-pus; other mesenteric glands were normal.

Ileo-colic and Colic Glands.—Normal.

Spleen.—The spleen showed on the surface half-a-dozen projecting nodules, the largest the size of a large pea; three of these were very prominent, projecting more than half their diameter from the surface; the others were completely surrounded by spleen pulp, and caused only slight projections; in the depth of the spleen three more nodules, the largest the size of a pea, were seen; all the nodules were caseous and softened throughout.

The gastro-splenic omentum was adherent to two of the projecting nodules, and showed between them about half-a-dozen millet-seed-sized caseous tubercles.

The lymphatic glands in the hilum of the spleen were perhaps slightly enlarged, but were not otherwise abnormal.

Liver.—The liver was normal in general appearance; on the surface under the capsule there were three caseous nodules, ranging from 1 to 2·5 mm. in diameter, the largest of which was softened; in the depth of the liver substance there was a nodule, 2 mm. in diameter, with a grey margin and bile-stained caseous centre.

In the Small Omentum, between the head of the pancreas and the liver, there were three enlarged glands; one of these was caseous almost throughout; the others contained soft yellow caseous nodules up to 3 mm. in diameter.

Kidneys and Suprarenal Bodies.—Normal.

Thorax.

Lungs.—The left lower lobe was enlarged, and filled the greater part of the left half of the thorax; it was practically everywhere adherent to the chest wall by adhesions which were recent and easily torn through, except at the apex, where the two layers of pleura were united more firmly; the right lung was free from adhesions.

On removal of the lungs the left lower lobe was firm, heavy and quite airless; on the dorsal surface of the apex there was a patch of thickening; externally the ventral thinner parts of the lobe had a greyish red translucent appearance, whilst the rest of the lobe showed a yellowish mottling; on section the whole of the lobe was in a condition of caseous pneumonia; the dorsal portions were almost uniformly caseous and softened, and in the midst of some of the caseous areas small cavities had formed; in the thin ventral portions a small amount of translucent greyish red tissue separated the caseous areas.

The upper lobes were adherent to the lower lobe, and were firm, red and airless except for a narrow margin along the dorsal border; these lobes contained a few caseous tubercles.

The upper and lower lobes were crepitant and congested on the dorsal surfaces; they contained sparsely scattered shotty caseous tubercles, with grey margins, ranging from about 1 to 2 mm. in diameter.

One of the small middle lobes was enlarged, firm and airless except at the extreme tip; on section it was advanced in caseation and beginning to soften. Another small middle lobe showed in the ventral part a caseous mass, 1·5 cm. in greatest diameter, with translucent margins; extending from this mass to the root of the lung

on the internal surface there was a reddish consolidated patch, which showed on section grey foci (? early caseation).

Pleura.—There were no tubercles on the pleura.

Heart and Pericardium.—Normal.

Bronchial Glands.—The glands on the right side were enlarged, congested and œdematous; one below the bronchus contained a minute caseous point; in the others there was no sign of caseation.

On the left side a prætracheo-bronchial gland, the size of a thrush's egg, was caseous and softened throughout; another slightly smaller gland in the root of the lung on the dorsal surface of the bronchus was also caseous throughout; an intertracheo-bronchial gland on this side was large, firm and congested, and contained one pin-head-sized caseous tubercle. Some glands along the trachea and a few ventral to the arch of the aorta were enlarged, congested, but were not otherwise abnormal.

Dorsal Mediastinal Glands.—Normal.

Axillary Glands.—One on the left side contained a softened yellow caseous nodule, 2 mm. in diameter; the others were normal.

Inguinal, Lumbar and Iliac Glands.—Normal.

Brain and Meninges.—Normal.

Testicles.—Normal.

Microscopical Examination (Smear Preparation).

Bronchial Gland.—Numerous tubercle bacilli.

Spleen.—Numerous tubercle bacilli.

Liver.—Numerous tubercle bacilli.

Axillary Gland.—Numerous tubercle bacilli.

RHESUS MONKEY 152.

Subcutaneous—Inoculation of an emulsion made with the spleen of Rhesus Monkey 132.

Date—June 7th, 1906.

Died—September 26th, 1906.

Duration of Experiment—111 days.

Clinical History.

The animal was inoculated in the subcutaneous tissue of the back on June 7th, 1906. After three weeks there was a small thickening in the subcutaneous tissue at the seat of inoculation and an opening in the skin over it from which issued a blood-stained purulent discharge; the axillary glands were not perceptibly enlarged. The tumour increased in size and the skin over it became ulcerated in several places. The glands in the axillae enlarged, the skin over them became adherent and finally ulcerated.

Until three weeks before its death the monkey was lively and ate well; it showed no sign of ill-health except that it increased very little in size. After the first manifestation of illness its condition became progressively and rapidly worse.

Post-mortem Examination.

Body.—In poor condition.

Local Lesion.—In the subcutaneous tissues over the lower part of the right scapula there was a small softened caseous tumour, the skin over which was pierced by a number of small openings through which caseo-pus could be made to exude; the hair was covered with masses of dried secretion. In the tissues around the tumour there was a number of discrete yellow softened nodules up to a hempseed in size.

Axillary Glands.—In the right axilla there was a group of three enlarged glands, the largest the size of a pigeon's egg, which on section were composed of creamy yellow caseo-pus and a fibrous wall varying in thickness; the skin over two of the glands was adherent and ulcerated, the floors of the ulcers being formed by the dried caseous contents of the gland.

In the left axilla there were two enlarged glands, one the size of a large pea, the other a little smaller, both of which were caseous and softened practically throughout.

Cervical Glands.—Normal.

Thorax.

Lungs.—The lungs were crepitant and collapsed normally, they contained moderately numerous nodules varying greatly in size, ranging from about the size of a pin's head up to about 1 cm. in diameter; most of the larger nodules had caseous and softened centres and relatively thick fibrous margins, but a few were composed of a firm greyish tissue containing purulent foci (resembling muco-pus); the smallest nodules were firm, grey, and had opaque yellowish centres.

Bronchial Glands.—Four (two on each side) were much enlarged and varied in size from 1 to 2 cm. in diameter; on section they were thin-walled cysts filled with soft yellow tenacious caseo-pus; the other bronchial glands were enlarged and one contained a miliary caseous tubercle.

Mediastinal Glands.—One of the ventral mediastinal glands on the right side, the size of a large pea, was caseous and softened throughout.

Vertebral Glands. On the right side of the vertebral column opposite the heads of the eighth to tenth ribs there was a prominent thin-walled tumour, the size of a thrush's egg, filled with thick caseo-pus; the right caudal lobe was closely adherent to the capsule of the tumour; other vertebral glands were normal.

Pleura.—Costal pleura, normal. The tendon of the diaphragm showed about half a dozen flattened nodules with fibrous margins and soft caseous centres, ranging in size from a millet seed to a hempseed.

Heart.—Normal.

Abdomen.

Omentum.—The omentum contained six nodules ranging in size from a pin's head to a hempseed; the larger ones were caseous and softened in the centre; the smaller ones were translucent.

Spleen.—The spleen contained two pea-sized yellow caseous and softened nodules with thin fibrous capsules and about a dozen smaller caseous nodules ranging in size from that of a pin's head to that of a hempseed. In the hilum of the spleen there were three enlarged glands, all of which were caseous and softened throughout.

Liver.—Sparsely scattered over the surface of the liver were grey translucent foci, the largest 1 mm. in diameter; these extended nearly their own diameter into the substance and did not project from the surface. In the substance there was a number of thin walled cysts, containing a greenish mucoid material, ranging in size from that of a pea downwards; there were besides a few caseous tubercles with fibrous margins.

Closely adherent to the head of the pancreas there was a mass of fused glands (probably including the portal) the size of a pigeon's egg; all the glands were entirely converted into thick yellow caseo-pus, which in each case was surrounded by a thin fibrous capsule.

Kidneys.—The left kidney showed in the depth of the cortex a minute grey tubercle. The right kidney showed a similar tubercle on the surface and three in the depth.

Suprarenal Bodies.—The right suprarenal body contained a firm yellow caseous nodule, 5 mm. in diameter. The left suprarenal body was normal.

Small Intestine.—The wall of the small intestine showed about eighteen thickened caseating patches, the largest of which extended transversely around nearly the whole circumference of the gut; the mucous membrane over them was ulcerated, the larger areas showing several separate ulcers. On the serous surface of the larger areas and in the mesentery there was a well-marked tuberculous lymphangitis.

Large Intestine.—The mucous membrane of the large intestine showed eight ulcers, with congested margins, the largest 1 cm. in greatest diameter; the bases of these ulcers were thickened (in some cases considerably) and fibroid and beset with soft caseous foci.

Mesenteric Glands.—The mesenteric glands were greatly enlarged and formed two large fluctuating tumours, one in the upper part, nodular in outline, about the size of a pigeon's egg, and one in the lower part about the size of a hen's egg; the two tumours were united together at the middle of the mesentery; the duodenum lay in close contact with the upper mass, but could be easily separated from it. On section all the glands composing the tumours were converted into thin-walled cysts filled with thick creamy caseo-pus; when the latter was washed away under a stream of water nothing was left but a multilocular cyst wall.

Ileo-colic Glands.—The glands on each side of the junction of the ileum and cœcum were enlarged and resembled on section the mesenteric glands.

Colic Glands.—Several of the colic glands (eight to ten in number) were enlarged, up to 1 cm. in diameter, caseous and softened throughout.

Ilio-sacral Glands.—Two ilio-sacral glands, the size of large peas, were yellow, caseous and softened throughout.

Lumbar Glands.—A left lumbar gland contained a millet-seed sized, soft, caseous tubercle.

Iliac Glands.—A left iliac gland, the size of a pea, was caseous and softened thoughout; the right was normal.

Inguinal Glands.—One on the left side resembled the iliac; the rest were normal.

Tongue, Tonsils, Pharynx, Submaxillary and Pharyngeal Lymphatic Glands.—Normal.

Microscopical Examination.

Lung Nodule.—Numerous tubercle bacilli.

Splenic Lymphatic Gland.—Very numerous tubercle bacilli.

MONKEY AND BABOON PASSAGE.

VIRUS B. IX.

MANGABEY MONKEY 4.

Fed on June 2nd, 1905, with 1·0 mg. of culture derived from the original material of Virus B. IX.

Killed.—August 25th, 1905. 84 days later.

Abstract of Post-mortem.

Tonsils and neck glands normal. The small intestine showed five tuberculous ulcers. The mesenteric glands were much enlarged, caseous throughout and softened. The lungs and spleen contained numerous caseous nodules, the largest the size of a pea. The liver was closely beset with caseous tubercles and there were several caseous tubercles in each kindey. One bronchial gland showed caseous areas; the rest were normal. The dorsal mediastinal and lumbar glands were extensively caseated, and there were areas of caseation in the portal, splenic and pancreatic glands. There were some tubercles on the omentum and pleural surface of the diaphragm.

A culture was isolated from a lumbar gland and used to feed Mandrill Baboon 68.

MANDRILL BABOON 68.

Fed with culture from Mangabey Monkey 4.

Dose.—0·1 milligramme.

Date.—October 13th, 1905.

Died.—November 28th, 1905. 46 days later.

Clinical History.

"Illness was first noticed on November 13th, 1905; he was much quieter and seemed to be losing appetite. These symptoms continued and he became thinner and lost strength. On November 20th he had a fit in the morning, suddenly losing power over his limbs; there was no loss of consciousness and only occasional slight twitchings of the legs; after a little while the symptoms abated and he was able to walk about and climb on to his perch. The fits recurred on every subsequent morning until death, and occasionally in the afternoon as well.

Post-mortem Examination.

Body in poor condition.

Tongue and Pharynx.—Normal.

Tonsils.—In one of the follicles of the right there was a little purulent material. (No tubercle bacilli found; numerous organisms stained blue.)

Left Tonsil.—Normal.

Right Retro-Pharyngeal Gland, about the size of a sparrow's egg, contained viscid tenacious yellow purulent material almost completely replacing the gland substance. (Tubercle bacilli found.)

Left Retro-Pharyngeal Gland.—Normal.

Submaxillary and Cervical Glands.—Normal.

Abdomen.

Omentum and Peritoneum.—Normal.

Stomach and Small Intestines.—Normal.

Large Intestines; mucous membrane congested; no ulceration.

Gastric, Mesenteric and Colic Glands.—Normal.

Spleen, Liver, Kidneys and Suprarenal Bodies.—Normal.

Thorax.

Heart and Pleura.—Normal.

Lungs and Bronchial Glands.—Normal.

The Muscles all over the body showed moderately numerous cysticerci (? taenia saginata); the tongue, the heart, and the wall of the stomach each contained one, and the diaphragm two.

The Brain contained numerous similar cysts; some were completely embedded in the cortical substance; others projected varying distances from the surface; the latter by their pressure had caused shallow cup-shaped hollows on the internal surface of the vault of the skull.

Microscopical Examination. (*Smear Preparations.*)

Retro-Pharyngeal Gland. Tubercle bacilli scanty.

Animals Inoculated.

Guinea-pig 1785, inoculated with an emulsion made from the spleen, died in 36 days of general tuberculosis.

A culture was isolated from a pharyngeal gland and, after cultivation on artificial media for 57 days, was used to inoculate three rabbits subcutaneously and to feed Monkeys 126 and 128.

The rabbits all died of general tuberculosis.

MONKEY 126.

Fed with culture obtained from the right retro-pharyngeal gland of Baboon 68.

Date—January 24th, 1906.

Dose—0·01 milligramme.

Died—May 24th, 1906. 120 days after the experiment began.

Clinical History.

The monkey remained well until about the end of April; he was then noticed to be quieter, and to have a "staring" coat.

He gradually became more depressed, and, although the appetite remained moderately good, slowly lost flesh and strength; there was no increase in the rate of respiration, and no diarrhœa.

Tuberculin Test.—April 10th, 1906, 76 days after the experiment began. Positive. Rise of temperature 1·9°C. Maximum 41·1°C. 3 hours after injection. Dose of tuberculin 2·0 cubic centimetres.

Temperature.—During the first twelve weeks the temperature was normal, varying from 39·3°C. to 38°C.; on April 17th it began to rise and for twelve days there was a period of moderately high pyrexia (maximum 41°C.); the temperature then became irregular and began gradually to fall; the daily fluctuations were often more than 2°C.; during the last few days the temperature was subnormal and on two occasions fell to 36°C.

Post-mortem Examination.

Body.—Slightly emaciated.

Tongue, Tonsils and Pharynx.—Normal.

Submaxillary, Pharnygeal and Cervical Glands.—Normal.

Abdomen.

The Peritoneal Cavity.—Contained about 15 cubic centimetres of clear fluid.

The Omentum.—Contained four yellow nodules, irregular in outline, each the size of hemp-seeds, which on section were entirely caseous and beginning to soften; there were, besides, four caseous tubercles, the size of millet seeds.

The Parietal Peritoneum was normal.

Stomach.—Normal.

Small Intestine.—One foot from the pylorus the wall of the small intestine showed a ring-like thickening, 13 mm. in width, which completely girdled the bowel and slightly constricted the lumen; the mucous surface was congested in patches and showed several irregular ulcers; on section all the coats of the intestine were found to be destroyed by caseation; the mesentery corresponding to the thickened intestine was almost completely obliterated, the intestine lying in close contact with the enlarged mesenteric glands; the lacteal vessels on the thickened intestine near the mesenteric attachment were opaque and yellow.

About a foot further along the intestine there was a raised area, 7 mm. in diameter, ulcerated in the centre; the submucous tissue beneath this area was caseous. Near the latter there was a small submucous caseous nodule, which was not ulcerated. Elsewhere the intestine was normal.

Large Intestine.—Normal.

Gastric Glands.—A gland near the cardiac end of the stomach was normal; one on the lesser curvature near the pylorus contained two soft caseous nodules, the largest 3 mm. in diameter.

Mesenteric Glands.—The mesenteric glands were much enlarged and formed a mass measuring $2\frac{1}{2} \times 2 \times 1\frac{1}{4}$ in.; this mass was composed of two thin walled, closely united, fluctuating swellings, one on each side of the mesentery; these swellings were smooth and shiny externally, showing a yellow mottling under the peritoneum, and were filled with soft creamy caseo-pus.

At the upper extremity of this mass, connected with the duodenum, were two glands, each 1 cm. in diameter, which were caseous and softened throughout.

The Ileo-Colic Glands.—Were œdematous, but were not otherwise abnormal.

Colic Glands.—Normal.

Thorax.

Lungs.—The lungs were expanded and filled the chest; they were somewhat emphysematous around the margins. The left lung was everywhere adherent to the chest wall; the adhesions were comparatively recent, except at one place posteriorly, where there was a tough adhesion not easily torn through; the right lung was free from adhesions.

The lobes of the left lung were adherent by recent adhesions. The right lobes were more firmly adherent together, and showed on the ventral and lateral surfaces a thin organised layer of lymph with a pitted or honeycombed surface.

The lung substance was closely beset with firm yellow nodules, ranging in size from rather less than 1 mm. up to 15 by 10 mm. in diameter; the great majority of the nodules, however, measured from 2 to 3 mm. in diameter; on section the nodules were homogeneously caseous throughout; several, particularly the larger ones, were surrounded by reddish patches of consolidation, otherwise the lung tissue between the nodules was crepitant.

Bronchial Glands.—The intertracheo-bronchial glands on each side were much enlarged, their substance being extensively replaced by softening caseous nodules, up to 4 mm. in diameter.

A Left Prætracheo-bronchial Gland, the size of a kidney bean, was partly caseous.

One on the right side contained one soft caseous nodule. A ventral mediastinal gland contained one pinhead-sized caseous tubercle.

Costal Pleura.—Normal.

On the Diaphragmatic Pleura there was some hypertrophy of the fringes around the margins of the tendon.

The Pericardial Sac.—Contained a small quantity of clear serous fluid.

Heart Muscle and Valves.—Normal.

Abdomen.

Spleen.—Not apparently enlarged, showed on the surface a few small flattened tubercles; under the capsule about a dozen nodules were seen ranging from 1·5 to 8 mm. in diameter; the larger ones projected considerably from the surface and were yellow, caseous, and softened throughout (one of these was adherent to the peritoneum covering the kidney); the smaller ones were also caseous but firmer, and the capsule over some of them showed filmy grey expansions. On section there were two or three caseous nodules in the depth of the spleen.

One Splenic Lymphatic Gland.—Contained two soft caseous nodules, the largest 2 mm. in diameter.

Liver.—Normal in general appearance, contained scattered yellow caseous and softened nodules with thin fibrous capsules, ranging from 2 to 5 mm. in diameter; twelve were counted on the surface, and there were a few in the depth, one larger (8 mm.) than the rest and very softened. At the bottom of the fissure between the right and left lobes there was a projecting yellow caseous nodule, 1 c.m in diameter.

The Portal Gland.—Appeared normal.

The Left Kidney.—Showed in the cortex five yellow caseous nodules, 2 to 3 mm. in diameter; four of these projected slightly from the surface. There were, besides, 3 or 4 caseous tubercles the largest the size of a pin's head.

The Right Kidney.—Contained two caseous nodules, the largest 3 mm. in diameter, and one small grey tubercle with an opaque centre.

The Right Suprarenal Body.—Showed in the cortex a softened caseous nodule 2.5 mm. in diameter.

Left Suprarenal Body.—Normal.

Lumbar Glands.—The lumbar glands on the left side, three in number, were much enlarged, caseous, and softened throughout; two were fused together and formed a mass the size of a filbert. On the right side two glands were slightly enlarged and practically caseous throughout.

Iliac Glands.—Normal.

Axillary and Inguinal Glands.—Normal.

Testicles.—Normal.

Brain.—Normal.

On the under surface of the dura mater, covering one of the cerebral hemispheres, there was a soft caseous tubercle.

Microscopical Examination (Smear Preparation).

Lung.—Numerous tubercle bacilli.

Spleen.—Numerous tubercle bacilli.

Dura Mater.—Numerous tubercle bacilli.

RHESUS MONKEY 128.

Fed with culture obtained from the right retro-pharyngeal gland of Baboon 68.

Date—January 24th, 1906.

Dose—0·0001 milligramme.

Killed—July 12th, 1906. 169 days after.

Clinial History.

The monkey remained well during the experiment. Weight at death, 4530 grammes.

Tuberculin Test.—April 10th, 1906, negative.

Post-mortem Examination.

There was no sign of tuberculosis in any of the organs or glands.

The Lungs showed under the pleura a few thin walled cysts containing the *Pneumonyssus griffithi.*

LEMUR PASSAGE.

VIRUS B. IX.

LEMUR 2.

Fed on June 2nd, 1905, with 1·0 mg. of culture derived from the original material of Virus B. IX.

Killed.—July 18th, 1905. 46 days later.

Abstract of Post-mortem.

There were sixteen ulcers in the small intestine and several ulcers in the cœcum; the glands in the neck, the mesenteric and colic glands were enlarged and caseous; the lungs contained four, the spleen twenty-four to thirty, caseous nodules; the liver showed scattered greyish white tubercles; the kidneys a few doubtful foci; the portal glands and a bronchial gland were tuberculous.

A culture was recovered from the mesenteric gland and inoculated into three rabbits and two lemurs (Nos. 10 and 12).

All the rabbits died of general tuberculosis of the usual type.

LEMUR 12.

Subcutaneous.—Inoculation of culture from Lemur 2.

Dose.—1·0 milligramme.

Date.—November 24th, 1905.

Killed, moribund. December 17th, 1905. 23 days after inoculation.

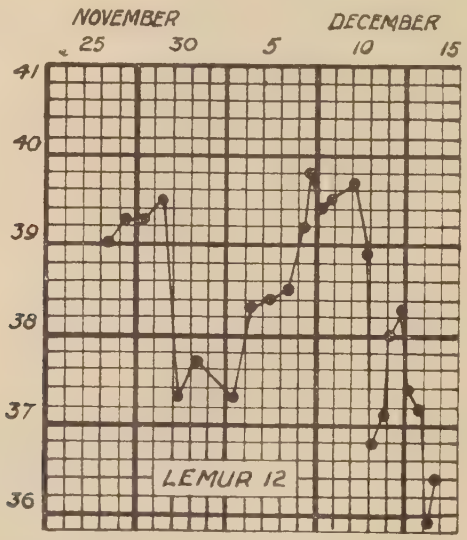
Clinical History.

The animal was inoculated subcutaneously between the shoulders on November 24th, 1905.

A fortnight after inoculation there was a hemispherical fluctuating swelling about 1¼ inches in diameter; a week later this had increased in size and the axillary glands on the left side were felt to be enlarged; on the right side enlarged glands could not be detected.

There was no obvious change in the general condition of the animal until December 16th, 22 days after inoculation, when it was found in the morning unconscious and collapsed; it remained in this state until the following morning and appeared to be dying; it was thereafter chloroformed.

Temperature.



Post-mortem Examination.

Body in fair condition; moderate amount of subcutaneous and abdominal fat.

Local Lesion.—At the seat of inoculation between the shoulders (more on the left than on the right side) there was a hemispherical cystic swelling about 1½ in. in diameter and 1 in. in depth; on section the tumour was a thin-walled cyst filled with chocolate-coloured pus; the internal surface of the cyst was yellow.

Axillary Glands.—In the left axilla there was a smooth fluctuating mass 1½ in. by ¾ in. by ½ in. composed of two or three glands fused together; on section these were converted into cysts filled with light brownish pus.

On the right side there was a gland the size of a sparrow's egg which contained a small cavity filled with pus.

Cervical Glands.—Left inferior cervical enlarged, no foci of necrosis seen. Other cervical glands normal.

Omentum and Peritoneum.—Normal.

Spleen.—(?) Enlarged, showed on the surface a grey speckled appearance; on section Malphigian bodies conspicuous, no tubercles visible.

Liver.—Pale; no tubercles seen.

Portal Gland.—Normal.

Kidneys and Suprarenal Bodies.—Normal.

Heart and Pleura.—Normal.

Lungs and Bronchial Glands.—Normal.

Tonsils, Pharynx, Intestines, and Mesenteric Glands.—Normal.

Microscopical Examination (Smear Preparation).

Spleen.—Moderately numerous tubercle bacilli.

A guinea-pig inoculated from the spleen died too early for the development of tuberculous lesions.

LEMUR 10.

Subcutaneous.—Inoculation of culture from Lemur 2.

Dose.—0·01 milligramme.

Date.—November 24th, 1905.

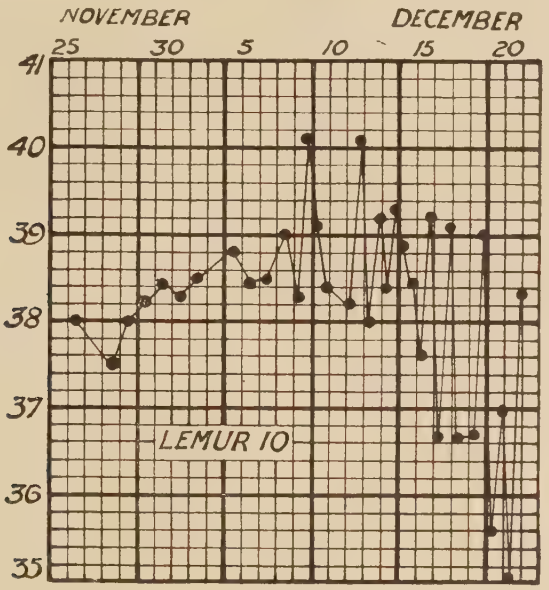
Died —December 24th, 1905. 30 days after inoculation.

Clinical History.

The animal was inoculated subcutaneously between the shoulders on November 24th, 1905. A fortnight after inoculation there was a prominent fluctuating swelling about ¾ in. in diameter; this increased in size, and on December 15th, 3 weeks after inoculation measured 1¼ in. in diameter; the skin on this date showed a small opening which discharged thin yellow pus. Subsequently the tumour increased a little in size; and the small opening became covered with dried secretion and only occasionally discharged pus. During the first three weeks there was no obvious enlargement of the axillary glands; at the end of the first month a gland in the right axilla was felt to be enlarged.

The general condition was not changed until towards the end of the experiment, when the animal suddenly became collapsed. During the last three days of life no temperature was recorded with the clinical thermometer.

Temperature.



Post-mortem Examination.

Body.—In fair condition. There was a large amount of fat in the omentum, covering completely the intestines, and also in the lumbar regions

Local Lesion.—At the seat of inoculation in the mid line of the back there was a soft tumour immediately under the skin (measuring 2 in. by 1½ in. by ½ in.). On section it was composed of soft granulation tissue with a cavity just beneath the skin containing clear serous fluid.

The Right Axillary Gland contained discrete caseous foci in the cortex; minute grey foci were seen in the left gland.

Cervical Gland on the right side was enlarged and in part softened without typical caseation. The corresponding gland on the left side was smaller and showed part of the cortex greyish white and firmer.

Abdomen.

The Spleen was a little enlarged and contained about fifteen discrete greyish miliary tubercles.

Liver.—On the surface of the liver nine grey submiliary tubercles could be seen.

Kidneys and Suprarenal Bodies appeared normal.

Thorax.

Heart.—Normal.

The Pleural Cavities were free from fluid.

Lungs.—The lungs contained two minute grey points of a doubtful nature.

Bronchial Glands.—Normal.

Lumbar, Iliac, Mesenteric, and Sternal Glands.—Normal.

DOG PASSAGES.

First Passage with Virus B. IV.

DOG 54.

A collodion capsule, containing an emulsion of culture derived from the original material of Virus B. IV. was put into the peritoneal cavity of the dog on May 30th, 1905.

The culture used was 21 days old, twenty-eighth generation, and was grown on ox serum.

The dog was killed on October 9th, 1905. 142 days after. During the last 6 to 8 weeks of life the dog gradually lost flesh, and when killed was very thin

Post-Mortem Examination.

Body.—Emaciated.

The Peritoneal Cavity.—Contained from 20 to 30 cubic centimetres of brownish turbid fluid.

The glass part of the capsule was found free in the peritoneal cavity; it was filled with whitish flocculent pus.

In the gastro-splenic omentum there was a firm mass the size of a small hen's egg; it lay between the stomach and the tail of the spleen, the latter partly encircling it; on section it was composed of fatty and fibrous tissue, showing here and there some suspicious yellow spots, but no definite caseation or necrosis.

In the centre of the mass were the remains of the collodion part of the capsule.

The Mesentery.—Showed a few small grey tubercles in the centre of some of the areas between the vessels. The surface of portions of the small intestine appeared to be covered with a thin transparent adherent layer: this layer did not cover the surface uniformly, but in several places was seen as small filmy islands.

Parietal Peritoneum.—Normal.

The Peritoneum.—Covering the diaphragm was thickened and showed dense white fibrous tissue containing faint yellow striæ.

The Liver.—Was adherent to the diaphragm and showed a patchy thickening of the capsule: on section the substance was normal.

The Portal Gland.—Seemed a little enlarged, but on section was not obviously tuberculous.

The Spleen.—Was enlarged and contained near the hilum several soft dirty yellowish nodules, up to a large pea in size: these appeared to have developed as the result of direct extension from the tumour.

Kidneys.—Each kidney showed in the cortex numerous tubercles ranging in size from 1 to 1·5 or more millimetres in diameter; many of the tubercles were elongated in a radial direction; they were grey and had minute opaque yellow centres.

The Lungs and Bronchial Glands.—Appeared normal.

The Ventral Mediastinal Glands.—Were enlarged and firmer than normal; on section there was no definite caseation, but from the cut surface a pus-like fluid could be scraped.

Mesenteric Glands and other Lymphatic Glands.—Were normal.

Microscopical Examination (Smear Preparations.)

Scraping from Tumour.—Numerous T.B., mostly in clumps.

Fluid from Glass Tube.—Numerous T.B.

Ventral Mediastinal Gland.—Numerous T.B.

Spleen Nodule.—A few T.B.

Mesenteric Gland.—No T.B.

Guinea-Pigs Inoculated.

No. 1736 was inoculated intraperitoneally with some of the contents of the glass part of the capsule and died in 54 days of general tuberculosis.

No. 1737, inoculated intraperitoneally with an emulsion made from the tumour, died of tuberculosis in 17 days.

DOG 82.

Fed with culture derived from Dog 54.

Dose.—32·5 milligrammes.

Date.—December 15th, 1905.

Killed.—March 16th, 1906. 91 days after.

Post-Mortem Examination.

Body.—In good condition.

Tongue, Pharynx and Tonsils.—Normal.

Submaxillary, Pharyngeal and Cervical Lymphatic Glands.—Normal.

Intestines, Large and Small.—Normal.

Mesenteric and Colic Glands.—Normal.

Spleen.—Normal.

Liver.—Normal.

Portal Gland.—Normal.

Kidneys.—Each kidney showed in the cortex numerous tubercles, ranging in size from about 0·5 to 1·5 mm. in diameter; the large tubercles were greyish and translucent and had in most cases minute opaque centres; the smaller tubercles were spherical, pearly grey, of greyish-white, and when cut into seemed to have narrow grey margins and soft whitish centres (these bodies were not apparently of a tuberculous nature).

The Lungs.—Were crepitant throughout; in one cephalic lobe a small firm nodule was felt; this on section had a reddish colour and was not, apparently, of a tuberculous nature; with this exception the lungs were normal.

Bronchial and Mediastinal Glands.—Normal.

All other Organs and Glands.—Were normal.

Microscopical Examination (Smear Preparations.)

Kidney Tubercle.—No T.B. (Preparation showed a large amount of fatty material.)

Lung Tubercle.—No T.B.

Guinea-pig Inoculated.

Guinea-pig 1935, inoculated with an emulsion made from the kidney, remained healthy.

DOG 92. (Age 6 to 12 months.)

Fed with culture from Dog 54.

Dose.—About 25 milligrammes.

Date.—January 22nd, 1906.

Killed.—March 27th, 1906. 64 days after.

Post-Mortem Examination.

Body.—In good condition.

Tonsils and Pharynx.—Normal.

Submaxillary Glands.—A gland at the left angle of the jaw contained a firm nodule, about 5 mm. in diameter, composed of greyish-red tissue and yellow streaks of necrosis; the gland on the right side was normal.

Pharyngeal Glands and Cervical Glands.—Normal.

Abdomen.

Omentum and Peritoneum.—Normal.

Stomach.—Normal.

Small Intestine.—Mucous membrane normal.

Large Intestine.—Normal.

Mesenteric Glands.—Normal in size; under the peritoneum covering one of the glands there was a doubtful yellow focus; on section nothing abnormal was seen in the substance of the gland (? fat in subperitoneal tissue); a piece of this gland was inoculated into a guinea-pig. Other mesenteric glands were normal.

Ileo-colic and Colic Glands.—Normal.

Liver.—Normal.

Spleen.—Normal.

Suprarenal Bodies.—Normal.

Kidneys.—The left kidney showed in the cortex on the surface a grey tubercle, about 1 mm. in diameter, with a minute opaque central point.

The left kidney contained a similar but smaller tubercle.

Thorax.

Heart and Pleura.—Normal.

The Lungs.—Contained from 10 to 12 hard caseous nodules, ranging in size from a little over 1 to 2·5 mm. in diameter; the nodules were somewhat irregular in outline and had grey translucent margins.

Bronchial and Mediastinal Glands.—Appeared normal.

All other lymphatic glands were normal in size and appearance.

Testicles.—Normal.

Microscopical Examination (Smear Preparations).

Lung Nodules (three examined).—In each a few T.B. were found.

Guinea-pigs Inoculated.

No. 1955, inoculated intraperitoneally with emulsion from mesenteric gland remained healthy.

No. 1954 inoculated intraperitoneally with emulsion from a lung nodule died in 18 days of tuberculosis.

SECOND PASSAGE WITH VIRUS B. IV.

DOG 56.

Age.—About six months.

A collodion capsule, containing an emulsion of culture derived from the mesenteric gland of Chimpanzee 8, was put into the peritoneal cavity of the dog on June 8th, 1905. The sub-culture used was 15 days old, sixth generation.

Killed when ill and emaciated, August 23rd, 1905. 76 days after the experiment.

Post-Mortem Examination.

Body.—Very emaciated.

The Peritoneal Cavity.—Was filled with yellow serous fluid containing a few small flakes of lymph.

In the Great Omentum.—There was an elastic tumour the size of a large hen's egg, firmly adherent to the floor of the abdomen along the mid-line; it was adherent also to the mesentery and to several coils of the small intestine, but from these it could with care be separated. On section the tumour was composed of soft granulation tissue showing many yellow areas of necrosis; the latter had a spongy fibrous texture, and from them turbid puriform fluid could be expressed. In the centre of the tumour the capsule lay embedded, the collodion part was brittle and partially disintegrated; the glass portion of the capsule was filled with turbid purulent fluid.

The serous surface of the mesentery was roughened and finely granular.

The Parietal Peritoneum.—In the lateral regions was profusely covered with tuberculous granulations; a thin layer of yellow lymph covered the peritoneal surface of the diaphragm.

The Spleen.—Was not enlarged; the pulp was pale and firm; on the surface were a few flakes of lymph.

Liver.—Capsule covered with a thin grey fibrinous membrane, thicker and yellower in patches; substance softer and paler than normal; no tubercles seen.

The Portal Gland.—Was much enlarged and showed in the cortex yellow patches of necrosis from which puriform fluid could be squeezed.

Kidneys.—Normal.

Lungs.—Were crepitant and closely beset with hard grey tubercles, the largest the size of a pin's head.

Bronchial and Mediastinal Glands.—Not obviously affected.

Mesenteric Glands and other Lymphatic Glands.—Were normal to the eye.

Microscopical Examination (Smear Preparations).

Tumour (necrotic patch) } T.B. extremely numerous.
Fluid from glass tube }

Portal Gland.—T.B. very numerous.

Guinea-pigs Inoculated.

No. 1647 was inoculated subcutaneously with some of the turbid fluid from the capsule.

No. 1648 was inoculated intraperitoneally with an emulsion made from the abdominal tumour.

Both guinea-pigs died, the first in 37 days, the second in 91 days, of general tuberculosis.

DOG 74. (Adult Retriever.)

Subcutaneous.—Inoculation of culture from Dog 56.

Dose.—10 milligrammes.

Date.—October 13th, 1905.

Killed.—December 10th, 1905. 63 days after inoculation.

Clinical History.

A tumour formed under the skin of the abdomen, which ulcerated. The inguinal and axillary glands enlarged; the skin over them became adherent and then ulcerated. 38 days after inoculation there was a discharging ulcer at the seat of inoculation, an ulcer in the groin and one in the left axilla; the left hind leg was drawn up, movement evidently causing pain; later the left fore-leg also became contracted.

Post-Mortem Examination.

Condition.—Good.

Local Lesion.—In the skin of the abdomen on the left side near the root of a nipple there was a small sinus discharging serous fluid; on section this was found to communicate with a space in the subcutaneous tissues, measuring 2 in. in length and 1 in. in breadth; the walls were in contact and were lined with soft pinkish granulation tissue.

In the left groin there was a linear cicatrix with a small sinus in the centre; pressure caused thin pus to exude from the latter; the sinus terminated at the left inguinal gland and was lined with granulation tissue discharging pus.

The Left Inguinal Gland.—Was indurated, but was otherwise normal to the eye.

In the Left Axillary Region.—There were two small openings in the skin in the centre of small cicatrices; on removal of the skin these were seen to communicate with a large cavity in the axilla lying under the pectoral muscle and extending dorsally as far as the scapula; the cavity was lined with soft granulation tissue and contained a small amount of pus.

The Left Axillary Gland.—Was about twice the size of the right; on section it appeared normal.

Spleen, Liver and Portal Gland.—Normal.

Kidneys.—Each kidney showed in the cortex on the surface a few opaque greyish white tubercles, the largest about 1·5 mm. in diameter; on section the latter were slightly elongated in a radial direction.

Thorax.

Lungs.—The lungs were crepitant and contained fairly numerous evenly distributed, hard grey tubercles, mostly about 1 mm. in diameter; the tubercles showed no sign of caseation.

Bronchial Glands.—Normal.

Heart and Pleura.—Normal.

Mesenteric, Iliac and other Peripheral Lymphatic Glands.—Normal.

Miscroscopical Examination.

Scraping from sinus in groin.—One tubercle bacillus.
Scraping from cavity in axilla.—No tubercle bacilli.

Guinea-pigs Inoculated.

No. 1809, inoculated intraperitoneally with a scraping from the wall of the cavity in the axilla, died in 9 days of an acute infection.

No. 1808, inoculated intraperitoneally with an emulsion from a bronchial gland, was killed 42 days later and showed general tuberculosis.

DOG 116. (Puppy.)

Fed with culture from Guinea-pig 1808, inoculated with an emulsion from the bronchial gland of Dog 74.

Date—March 29th, 1906.

Dose—10 milligrammes.

Killed—July 5th, 1906, 98 days after the experiment began.

Clinical History.

The dog gradually lost appetite, and at the end of the first month had become very emaciated; its appetite then improved, and it began slowly to put on flesh; when killed it was in moderately good health.

Tuberculin Test.—May 10th, 1906. 42 days after the experiment began. Negative. Dose of tuberculin, 5·0 cc.

Post-Mortem Examination.

Tonsils and Pharynx.—Appeared normal.

Submaxillary Glands.—Normal.

Left Retro-Pharyngeal Gland.—Was enlarged and indurated; on section it showed at one extremity a large greyish white somewhat translucent patch containing irregular opaque whitish areas of caseation, some of which were beginning to soften; the cortex of the rest of the gland showed similar but smaller patches; one of these was greyish white and not caseous.

Just posterior to this gland was a small gland (cervical), the substance of which was almost completely replaced by a large greyish white patch, in the midst of which was an irregular opaque white caseous mass beginning to soften. Other cervical glands on this side were normal.

Right Retro-Pharyngeal Glands.—Showed patches in the cortex similar to those in the left pharyngeal; they replaced about half the substance of the gland.

Right Cervical Glands.—Normal.

Parotid Glands.—Normal.

Abdomen.

Omentum and Peritoneum.—Normal.

Intestines.—Scattered throughout the whole length of the small intestine in the submucous tissue were fairly numerous yellow foci, largest less than a millet seed in size, which could just be felt between the finger and thumb (smears from two of these showed no tubercle bacilli but numerous other organisms stained blue). All the Peyer's patches were normal and there was no ulceration anywhere.

Large Intestine.—Normal.

Gastric Glands.—Normal.

Mesenteric Glands.—The mesenteric glands seemed a little enlarged. The glands in the anterior part of the mesentery were normal except for one or two small grey foci. Passing backwards, the glands became more and more severely affected. Those in the middle of the mesentery showed around the cortices sharply defined greyish-white semi-opaque areas, varying much in size, the larger ones containing opaque white friable caseous patches or streaks. The terminal mesenteric gland and the ileo-colic glands showed almost the whole of the peripheral part of the cortex composed of greyish-white caseating tissue.

Colic and Rectal Glands.—Normal.

Spleen.—Was a little soft but not apparently enlarged; on the surface there was a small group of pearly white granules; on section the Malpighian bodies were conspicuous but there were no foci of necrosis.

Liver.—Was normal in general appearance, and showed minute grey foci sparsely scattered throughout; there were besides a grey tubercle the size of a millet seed and an opaque white tubercle about 0·5 mm. in diameter (tubercle bacilli found).

Portal Gland.—Normal.

Kidneys and Suprarenal Bodies.—Normal.

Thorax.

The lungs collapsed normally and showed no patches of consolidation; they contained, evenly distributed throughout, moderately numerous firm grey nodules ranging in size from a millet seed to that of a small pea; most of the nodules were opaque and caseous in the centre; three of the larger nodules were greyish red and showed small cavities in their interior containing a small quantity of semi-purulent material.

The bronchial glands were distinctly enlarged; one on the left side showed in the cortex an opaque pinhead-sized caseous focus; an intertracheo-bronchial gland contained a minute yellow point.

Heart and Pleura.—Normal.

Prepectoral, Prescapular, and Inguinal Glands.—Normal.

Iliac and Lumbar Glands.—Normal.

Microscopical Examination (Smear Preparations).

Left Tonsil.—No tubercle bacilli.

Mesenteric Gland.—Numerous tubercle bacilli.

Liver (large grey tubercle).—No tubercle bacilli.

Liver (white tubercle).—Seven tubercle bacilli.

Intestine (two smears).—No tubercle bacilli.

Lung (two nodules).—Numerous tubercle bacilli.

Animals Inoculated.

Guinea-pigs 2137 and 2138 inoculated intraperitoneally with emulsions made from lung nodules became tuberculous.

VIRUS B. IV. PASSAGE.

DOG 18.

Fed on August 23rd, 1904, with an emulsion made from the organs of Guinea-pigs 1148 and 1150, inoculated with milk of Cow 164.

Dose—10·15 million tubercle bacilli.

Killed—January 5th, 1905, 135 days later.

Post-Mortem Examination.

Two mesenteric glands were enlarged and tuberculous, and there were a few doubtful tubercles in the lungs.

A culture was isolated from a mesenteric gland and used to inoculate a series of rabbits (*see* page 104) and to feed Dog 132.

DOG 132.

Fed with culture obtained from Dog 18.

Date—June 1st, 1906.

Dose—50 milligrammes.

Initial Weight—7470 grammes. Final weight, 8,900 grammes.

Killed—August 17th, 1906, 77 days later.

Post-Mortem Examination.

Pharynx and Tonsils.—Normal.

Pharyngeal Glands.—The left pharyngeal gland contained a single small caseous focus; the right was normal.

Submaxillary and Cervical Glands.—Normal.

Intestines.—Normal.

Mesenteric Glands.—All the mesenteric glands with the exception of two in the anterior part of the mesentery contained small irregular patches and foci of caseation; these were situated in the cortex just beneath the capsule.

Ileo-Colic and Colic Glands.—Normal.

Spleen.—Normal.

Liver.—Normal.

Portal Gland.—Normal.

Kidneys.—Normal

Lungs.—In the left lung there was a grey miliary tubercle with a yellow caseous centre and also a minute slightly opaque grey tubercle; the rest of the lung was normal.

Bronchial Glands.—One on the right side contained an opaque caseous focus. One on the left side contained an irregular caseous tubercle.

Heart and Pleura.—Normal.

Microscopical Examination (Smear Preparations).

Mesenteric Gland.—A few tubercle bacilli.

Bronchial Gland.—No tubercle bacilli.

PASSAGE WITH VIRUS B. IX.

DOG 60. (Puppy.)

Fed on July 10th, 1905, with 1 mg. of culture derived from the original material of Virus B. IX.

Killed.—October 30th, 1905, 112 days later.

Abstract of Post-mortem Examination.

Tonsils and Intestines.—Normal.

The Pharyngeal, and Ileo-colic Glands contained a few discrete opaque white slightly gritty caseous tubercles; three or four mesenteric glands contained dense irregular caseous nodules, up to about 2 mm. in diameter.

There was no sign of tuberculosis in the internal organs.

A culture was isolated from a mesenteric gland nodule and inoculated into a series of rabbits and Dog 84 (by feeding).

All the rabbits died of general tuberculosis.

DOG 84. (Puppy.)

Fed with culture derived from a mesenteric gland of Dog 60.

Dose.—50·0 milligrammes.

Date.—January 2nd, 1906.

Killed.—March 16th, 1906, 73 days later.

Post-Mortem Examination.

Tonsils and Pharynx.—Normal.

Submaxillary, Pharyngeal and Cervical Glands.—Normal.

Small Intestine.—Most of the Peyer's patches showed a number of minute yellow points in the substance, but were not otherwise abnormal.

Large Intestine.—Normal.

Mesenteric and Colic Glands.—Normal.

Spleen, Liver, Kidneys and Suprarenal Bodies.—Normal.

Portal and Cœliac Glands.—Normal.

Heart and Pleura.—Normal.

Lungs.—Normal in general appearance, contained scattered hard grey miliary tubercles, many of which showed a minute opaque point in the centre.

Bronchial Glands.—Normal.

Microscopical Examination (Smear Preparations).

Peyer's patch.—2 T.B.

Lung tubercle.—No T.B.

Guinea-pig Inoculated.

A guinea-pig (No. 1936) inoculated intraperitoneally with an emulsion made from the lung, died in 40 days of general tuberculosis.

DOG 130.

Subcutaneous (partly intraperitoneal) inoculation of culture, 7th generation, 21 days old, isolated direct from the mesenteric gland of Dog 60.

Date.—May 17th, 1906.

Dose.—48 milligrammes.

Weight.—Initial weight 4,570 grammes. Final weight 4,500 grammes.

Died.—August 10th, 1906, 85 days after inoculation.

Post-Mortem Examination.

Local Lesion.—In the skin of the abdomen in the middle line there was an oval ulcer measuring 1 in. by 1¾ ins. It was perfectly clean and was in process of healing. At the posterior extremity the edge was undermined forming a sinus lined with granulation tissue which led down to a left inguinal gland.

In the skin of the left inguinal region there were two small ulcers with granulating sinuses leading to the glands and on the right side one ulcer and sinus. The subcutaneous tissues on both sides were œdematous.

The inguinal glands on both sides were a little enlarged and the cortices were moist and yellow in colour.

Thorax.

Heart and Pleura.—Normal.

The Lungs were congested and œdematous, but floated in water; the substance had a grey translucent appearance.

Bronchial Glands.—Normal.

Ventral Mediastinal Glands.—Slightly enlarged and œdematous.

Abdomen.

The Peritoneal Cavity.—Was distended with a large quantity of clear serous fluid.

The Omentum was thickened by a network of soft grey translucent tissue.

The Mesentery and Meso-colon showed a few scattered minute translucent tubercles.

Spleen.—Appeared normal.

Liver.—The substance of the liver was infiltrated with grey translucent tissue forming a close network.

The Portal Gland was enlarged and was distinctly yellow and necrotic throughout.

The Kidneys contained scattered grey foci in the cortices: on section some of these extended radially through the cortex.

Suprarenal Bodies.—Normal.

Lymphatic Glands.

Axillary, Submaxillary and Cervical Glands.—Œdematous but otherwise normal in appearance.

Mesenteric Glands were œdematous and had a uniform yellow appearance.

Iliac Glands on both sides were œdematous and the left contained a yellow necrotic area.

Microscopical Examination (Smear Preparations).

Liver, Kidney, Spleen, Omentum, Mesenteric Gland, Right Inguinal Gland.—All contained numerous tubercle bacilli.

Lung.—Showed a moderate number of tubercle bacilli, mainly in clumps and cells.

PASSAGE WITH VIRUS B. IX.

DOG 50. (Adult.)

Fed on June 2nd, 1905, with 1 mg. of culture derived from the original material of Virus B. IX.

Killed.—September 21st, 1905, 111 days later.

Abstract of Post-Mortem Examination.

Tonsils and Intestines.—Normal.

Neck Glands and Abdominal Lymphatic Glands.—Normal.

Lungs.—The left cephalic lobe was consolidated and showed a small cavity near the apex containing a small quantity of pus; the left bronchial gland was a little enlarged.

Each kidney contained a few opaque white spherical tubercles, the size of small pins' heads (not tuberculous).

Animals Inoculated.

Two guinea-pigs were inoculated, one No. 1708 with some of the pus from the cavity, the other No. 1707 with an emulsion made from the consolidated lung; both became tuberculous and cultures were isolated from each.

A series of rabbits and a calf No. 374 were inoculated with the culture isolated from Guinea-pig 1708, and two dogs were inoculated, one subcutaneously, the other by the mouth, each with 10 mg. of the culture obtained from Guinea-pig 1707.

Abstracts of the post-mortem notes of the rabbits are given on page 177.

CALF 374.

Subcutaneous.—Inoculation of culture, third generation, 20 days old, derived from the lung of Dog 50, through Guinea-pig 1708.

Date.—January 2nd, 1906.

Dose.—50 milligrammes.

Weight.—1 cwt. 2 qrs.

Killed.—April 3rd, 1906, 91 days after inoculation.

Clinical History.

The calf was inoculated subcutaneously on the left side of the neck on 2nd January, 1906.

A fortnight after inoculation there was a prominent firm rounded swelling, 3½ inches in diameter; the prescapular gland measured about 4 inches in long diameter.

There was no further increase in size, but during the latter part of the experiment the tumour diminished a little and began to soften.

The prescapular gland also diminished a little in size and became very hard and nodular.

About seven weeks after inoculation an enlarged prepectoral gland was felt.

There was no disturbance in the general health of the calf during the experiment.

Tuberculin Test.—March 23rd, 1906. Eighty days after inoculation. Positive. Rise of temperature, 2·4°C.

Weights.

There was a steady gain in weight during the experiment:—

January 2nd, 1906	-	1 cwt. 2 qrs.	0 lbs.
January 25th, 1906	-	1 cwt. 2 qrs.	11 lbs.
February 6th, 1906	-	1 cwt. 2 qrs.	27 lbs.
February 21st, 1906	-	1 cwt. 3 qrs.	22 lbs.
March 20th, 1906	-	2¼ cwts. 1 qr.	4 lbs.
April 3rd, 1906	-	2¼ cwts. 1 qr.	25 lbs.
Gain in weight	-	3 qrs.	25 lbs.
Rate of gain per week			8·4 lbs.

Temperature.

The temperature remained practically normal throughout the experiment.

Post-Mortem Examination.

Carcass in good condition.

Local Lesion.—At the seat of inoculation on the left side of the neck there was a hemispherical tumour, measuring 3 in. by 3 in. by 1¼ in., composed of a mass of dense yellow caseated tissue, slightly gritty around the margins, surrounded by a zone of fibrous tissue about 3 mm. in greatest thickness; under the skin the mass was separated from its capsule by a layer of thick caseo-pus, but elsewhere was firmly adherent; the fibrous capsule was adherent to the skin, which was thickened, and to the muscles.

The Left Prescapular Gland measured 3¼ in. by 2 in. by 1¼ in., and was very hard and irregular in outline; attached to the convex surface there was a short fibrous cord, the thickness of a crow quill, with caseo-calcareous centre; on section the gland was composed partly of dense gritty caseous masses and partly of fibro-calcareo-caseous tissue; on the convex surface the capsule was greatly thickened, measuring at one place 1 cm. in thickness.

Right Prescapular Gland.—Normal.

Prepectoral Glands.—On the left side the spherical gland was enlarged and contained an irregular calcareo-caseous mass, the size of a kidney-bean, with a fibrous margin; other prepectoral glands on this side were normal.

Right Prepectoral Glands.—Normal.

Cervical Glands.—A gland in the middle of the neck on the left side, the side of a broad bean, showed about half its substance calcareo-caseous. Other cervical glands on this side as well as those on the right side were normal.

Abdomen.

Omentum und Peritoneum.—Normal.

Spleen.—Weight, 20 ounces, normal on the surface and on section.

Liver.—Normal.

Gall-Bladder.—Normal.

Portal Glands.—One contained a number of yellowish-white foci, not perceptibly gritty; another gland contained three or four small very gritty tubercles; in a third gland there was one gritty tubercle.

Left Kidney.—Showed on the surface a minute greyish white focus.

Right Kidney.—Normal.

Suprarenal Bodies.—Normal.

Thorax.

Heart and Pleura.—Normal.

Lungs.—The lungs were normal in general appearance. In the left caudal lobe under the pleura three grey miliary tubercles were seen; one of these had a calcareous centre; besides these there were a few minute transparent points (? tubercles); in the rest of the lung one or two grey points similar to the latter were seen. No tubercles were seen on section.

The Bronchial and Dorsal Mediastinal Glands.—Contained scattered yellow calcareous tubercles, the largest the size of a pin's head.

Infra-tracheal and Ventral Mediastinal Glands.—Normal.

Larynx and Trachea.—Normal.

Tongue, Tonsils and Pharynx.—Normal.

Intestines.—Normal.

Urinary Bladder.—Normal.

Testicles.—Normal.

Thyroid Body.—Normal.

Eyes.—Normal.

Special Lymphatic Glands.

One Coeliac Gland.—Contained a small yellow slightly gritty tubercle.

An Ileo-Colic Gland.—Showed in the cortex two irregular yellow calcareous tubercles.

The Mesenteric, Colic, Gastric, Precrural, Popliteal, Gluteal, Pudic, Iliac, Ilio-Sacral, Lumbar, Renal, Sub-Maxillary, Left Pharyngeal, Mastoid and Axillary.—Were normal.

The Right Pharyngeal Gland.—Contained one small irregular calcareous tubercle.

Microscopical Examination.

Prescapular Gland.—Moderate number of tubercle bacilli.

Pharyngeal Gland.
Portal Gland.
Coeliac Gland.
Lung.
} No tubercle bacilli.

Animals Inoculated.

Guinea-pig 1959, inoculated with an emulsion made from the spleen, died in 37 days and showed general tuberculosis.

Calf 394 was inoculated subcutaneously with 20·5 c.c. of an emulsion made from the prescapular gland.

CALF 394.

Subcutaneous inoculation of an emulsion made from the prescapular gland of Calf 374.

Dose.—83·7 million tubercle bacilli.

Date.—April 3rd, 1906.

Weight.—1 cwt. Age, 8 weeks.

Killed.—June 6th, 1906. 64 days after inoculation.

Clinical History.

The calf was inoculated subcutaneously on the left side of the neck on April 3rd, 1906.

A week later a slight indefinite subcutaneous thickening, measuring about 2 by 1, was felt; the prescapular gland was very slightly enlarged.

The thickening gradually diminished and at last became imperceptible and the gland resumed its normal size.

The calf during the whole of the experiment suffered from diarrhœa which was especially severe in the last month.

The temperature remained practically normal through out (maximum 39·6°C.)

Tuberculin Test.—May 31st, 1906. 58 days after inoculation.—Negative.

Dose of tuberculin about 1 cc.

Weights.

During the first three weeks there was a gain in weight of 2 lbs.; in the last 43 days there was a loss of 7 lbs.

April 3rd and 18th, 1906 -	1 cwt.	0 qrs.	0 lbs.
April 24th, 1906 -	1 cwt.	0 qrs.	2 lbs.
May 15th, 1906 -	0 cwt.	3 qrs.	27 lbs.
June 6th, 1906 -	0 cwt.	3 qrs.	23 lbs.
Loss in Weight -	0 cwt.	0 qrs.	5 lbs.

Post-Mortem Examination.

Condition.—Moderate.

Local Lesion.—In the subcutaneous tissues on the left side of the neck there was a very thin patch of fibrous tissue, about 1 in. in diameter, beset with discrete tubercles, the largest the size of a millet seed; the tubercles were grey, the smallest ones being almost transparent, the largest slightly opaque, though not definitely caseous, in the centre.

The Left Prescapular Gland was normal in size and nothing abnormal was seen on section.

Right Prescapular.—Normal.

Prepectoral and Cervical Glands.—Normal.

Thorax.

Parietal and Visceral Pleura.—Normal.

Lungs.—Normal except for two or three collapsed lobules.

Bronchial and Mediastinal Glands.—Normal.

Heart and Pericardium.—Normal.

Abdomen.

Omentum and Peritoneum.—Normal.

Spleen.—Weight 4½ ozs.—Normal.

Liver.—Normal.

Portal Glands.—Normal.

The Right Kidney showed on the surface of a lobule a group of about ten grey foci, the largest a little more than 1 mm. in diameter; on section these extended into the cortex in a radial manner; the larger ones were yellowish in the centre.

Left Kidney and Suprarenal Bodies.—Normal.

Tonsils, Pharynx and Intestines.—Normal.

Submaxillary, Pharyngeal, Gastric, Mesenteric and Ileo-Colic Glands.—Normal.

Testicles.—Normal.

Various Lymphatic Glands.

Cœliac, Lumbar, Renal, Iliac, Precrural, Pudic, Popliteal, Axillary and Parotid Glands.—Normal.

DOG 110. (Adult Retriever.)

Subcutaneous inoculation of culture derived from Guinea-pig 1707, inoculated with an emulsion made from the lung of Dog 50.

Date.—March 21st, 1906.

Dose.—Slightly less than 10 milligrammes.

Killed.—June 28th, 1906, 99 days after inoculation.

Clinical History.

The dog was inoculated subcutaneously in the right flank.

Fifteen days later there was a flat tumour measuring about 3 in. by 1¾ in., showing at one part a deep ulcer, 1½ in. by 1¼ in., with slightly everted margins and floor formed by soft granulation tissue; there was a discharge of pus from the ulcer.

On April 12th, 1906, the ulcer was the size of a five-shilling piece and had abrupt clean cut margins. It then began to diminish in size; on May 10th, it was shallower and about ¾ in. in diameter and at the end of the experiment had almost disappeared.

On May 10th, a doughy swelling was noticed in the right axilla, the skin over which showed two or three small ulcers.

The general health of the animal was unaffected by the inoculation.

Tuberculin Test.—May 10th, 1906. 50 days after inoculation. Dose of tuberculin 5·0 cc. The temperature rose 1° C. twelve hours after injection.

Post-Mortem Examination.

Body in good condition.

Local Lesion.—The skin of the abdomen on the right side showed a superficial ulcer, about ⅛ in. in diameter, with a pale granular floor; on the under surface of the skin around the ulcer there was a ring of white fibrous tissue from the margins of which strands of fibrous tissue radiated in all directions, giving a puckered appearance.

The Axillary and Inguinal Glands were normal in size and general appearance.

Thorax.

Lungs.—The lungs contained two grey slightly opaque tubercles the size of rape seeds; otherwise the lungs were normal.

Bronchial Glands.—Normal.

Heart and Pleura.—Normal.

Abdomen.

Spleen.—Normal.

Liver.—A grey point was seen in the liver.

Portal Gland.—Was normal.

Kidneys.—Each kidney showed in the cortex scattered grey tubercles, with opaque centres, the largest about 1·5 mm. in diameter (not apparently tuberculous).

Suprarenal Bodies.—Normal.

A Mesenteric Gland.—Contained a yellow speck.

Other Lymphatic Glands.—Normal.

Microscopical Examination (Smear Preparations).

Liver.—No tubercle bacilli.

Kidney.—No tubercle bacilli.

Mesenteric Gland.—No tubercle bacilli.

Lung.—Two tubercles.

DOG 108. (Adult Retriever.)

Fed with culture obtained from Guinea-pig 1707 (inoculated with an emulsion made from the lung of Dog 50); the culture was mixed with sterilized milk.

Date.—March 21st, 1906.

Dose.—10 milligrammes.

Killed.—June 27th, 1906, 98 days after.

Clinical History.

There was no sign of illness during the experiment.

Tuberculin Test.—May 10. 50 days after the experiment began. Positive. Rise of temperature, 1·3°C. Dose of tuberculin, 5·0cc.

Post-mortem Examination.

There was no tuberculosis of the mucous membrane of the alimentary tract or of the glands in connection with it.

Spleen.—Contained a pea-sized nodule which projected from the surface; on section the nodule consisted partly of spleen tissue and partly of soft greyish substance (? lymphoid); no tubercle bacilli were found in a smear.

Liver, Kidneys, and Suprarenal Bodies.—Were normal.

Thorax.

Lungs.—In the lungs there was one grey somewhat opaque submiliary tubercle; otherwise the lungs were quite normal.

Bronchial Glands.—Normal.

All other Organs and Glands.—Normal.

Microscopical Examination (Smear Preparations).

Lung.—No tubercle bacilli.

Spleen.—No tubercle bacilli.

DOG PASSAGE WITH VIRUS B XXII.

DOG 72.

Inoculated intraperitoneally on September 4th, 1905, with culture derived from the original material through Guinea-pig 1509.

Dose.—1·0 milligramme.

Killed.—February 7th, 1906, 156 days after inoculation.

Post-mortem Examination.

There were a few nodules and some fibrous tubercles in the lungs, a few yellow foci in the liver, and some doubtful tubercles in the kidneys.

A culture was isolated from one of the lung nodules and used to inoculate a series of rabbits and Dog 126.

All the rabbits died of general tuberculosis.

DOG 126.

Subcutaneous inoculation of culture, 2nd generation, 22 days old, derived from the lung of Dog 72.

Date.—May 9th, 1906.

Dose.—10 milligrammes.

Weight.—Initial weight 4,850 grammes. Final weight 6,000 grammes.

Killed.—August 16th, 1906, 99 days after inoculation.

Post-mortem Examination.

Local Lesion.—In the skin of the abdomen to the right of the middle line there was a small, flat, granulating ulcer.

In the skin over the inguinal glands there were three small apertures, two on the right and one on the left, which communicated with sinuses in the periglandular tissues.

The inguinal glands were not enlarged; in the cortices there were a few fine, wavy, yellowish-white streaks.

Thorax.

Heart and Pleura.—Normal.

Lungs.—In the superficial part of the lung substance there were three translucent miliary tubercles.

Bronchial Glands.—Were small, one contained in the cortex a few whitish lines, a second contained a small irregular caseous focus.

Mediastinal Glands.—Normal.

Abdomen.

Peritoneum.—Normal.

Spleen.—Normal.

Kidneys.—Normal.

Liver.—Contained numerous translucent tubercles up to about 1 mm. in diameter; occasionally a tubercle showed a minute central opacity.

Portal Glands.—Normal.

Special Lymphatic Glands.

Mesenteric, Iliac, Lumbar, Submaxillary and Axillary Glands.—Normal

Microscopical Examination (Smear Preparations).

Liver.—A few scattered tubercle bacilli seen.

Lung.—No tubercle bacilli seen.

Bronchial Gland.—No tubercle bacilli seen.

PIG PASSAGE.

PIG 8.

Fed from October 1st, 1902, to December 31st, 1902 (92 days) with tuberculous milk of Cow 40.
Killed.—June 4th, 1903. 247 days after the experiment began.

Abstract from Post-Mortem Notes.

There were two or three submucous nodules in the small intestines, one of which was caseous; there was no ulceration; the mesenteric, pancreatic and ileo-colic glands were enlarged and caseous, and there was slight tuberculosis of the lungs, thoracic glands and liver.

Animals Inoculated.

An emulsion was prepared from the mesenteric glands and a pancreatic gland and inoculated into Pigs 10 and 12 and Calves 104 and 106.

PIG 10.

Subcutaneous.—Inoculation of an emulsion made from the mesenteric glands of Pig 8.
Dose of Emulsion.—10 cubic centimetres (no tubercle bacilli were found in the emulsion).
Date.—June 4, 1903.
Weight on June 9, 1 qr. 16 lbs.
Killed.—October 8, 1903. 126 days after inoculation.

Clinical History.

The pig was inoculated subcutaneously on the inner side of the left thigh on June 4th, 1903.

A month after inoculation there was a subcutaneous thickening about ¾ inch in breadth with a cord-like prolongation into the groin.

On July 28th, 54 days after inoculation a small nodular mass was felt, around which was grouped a number of tubercles of various sizes; the skin was freely movable. Subsequently the mass increased a little in size and the tubercles in number.

The animal showed no signs of ill-health during the experiment.

Post-Mortem Examination.

Carcass.—In moderately good condition.

At the Seat of Inoculation.—On the inside of the left thigh, there was a small irregular tumour surrounded by a number (two or three dozen) of hard tubercles. The skin was freely movable over the tumour, but was adherent to a few of the tubercles. On section the tumour measured 1½ in. by 1 in., and showed fibrous tissue enclosing softened caseous gritty material and a few discrete tubercles. The subcutaneous tubercles ranged in size from a pin's head to a small pea; each had a caseous gritty centre and a pinkish translucent periphery.

Similar tubercles infiltrated the underlying muscle.

Stretching from the under surface of the local tumour to the brim of the pelvis there was a thick cord; the distal end of the cord was one-third of an inch in diameter, and was composed of a pinkish translucent tissue, showing here and there a caseous focus, deposited around a thickened lymphatic vessel: the proximal end was narrower, and showed isolated tuberculous deposits.

Inguinal Glands.—The glands (five or six in number) in the left inguinal region, were fused together to form a mass weighing a little over an ounce, and measuring 3 in. by 1 in. by 1½ in. On section they consisted of dense whitish caseous substance, slightly gritty from calcification; all the glands were easily shelled out from their capsules.

Iliac Glands.—The glands (six to eight in number) in the left iliac region were enlarged, and formed a mass 3 in. by 1 in. by ¾ in.: the larger ones contained numerous dense greyish white caseous masses, slightly gritty from calcification, the smaller ones were similarly, but not so extensively affected.

The Gland at the bifurcation of the aorta showed similar areas.

The Right Inguinal and the Right Iliac Glands.—Were not enlarged and showed no visible tubercles.

Abdomen.

In the Omentum, close to its attachment to the stomach were half-a-dozen tubercles ranging in size from a pin-head to a small pea; the small ones were grey and translucent; the large ones caseous and calcareous.

The Peritoneum covering the anterior surface of the stomach (in contact with the liver) showed a number of minute hard translucent granules. Elsewhere the peritoneum and omentum were normal.

Hepatic Glands.—Between the stomach and the anterior margin of the pancreas there was a mass of enlarged glands, from ½ in. to 1½ in. in length; this group of glands was continuous with the group in the hilum of the liver; all showed irregular caseous areas, as in the iliac glands, the smaller glands being less affected than the larger.

Gastric Glands.—Under the peritoneum on the posterior aspect of the stomach there were several enlarged glands, and a mass 2¼ in. by 1 in. tuberculous throughout.

Mesenteric Glands.—At the lower end of the mesentery, there were three enlarged glands, showing caseating areas, gritty from calcification. Other mesenteric glands and glands along the large intestine were normal.

Large and Small Intestine, Tongue, Tonsils, Pharynx, Larynx.—Normal.

Spleen.—Weighed 3 ozs. On the surface, and apparently growing in the capsule, were four small grey translucent tubercles; in the parenchyma there were between twenty and thirty tubercles, ranging in size from a pin-head to a small pea; on section they were all caseous and gritty. Some of these tubercles caused projections from the surface and one little group (an eighth of an inch in diameter) was surmounted by a vascular tuft.

Splenic Lymphatic Glands.—Near the centre of the hilum there was a gland the size of a filbert, showing gritty caseating areas.

Liver.—Weighed 1lb. 12oz; beneath the capsule, and moderately evenly distributed throughout the parenchyma, were numerous tubercles; the larger ones, the size of a small pea, had on section a lobular outline, appearing as if made up of several tubercles; they were for the most part greyish, firm and homogeneous throughout; a small proportion, however, showed yellow calcareous centres.

Hepatic Glands.—(*See* above).

Kidneys.—Normal.

Suprarenal Bodies.—Normal.

Thorax.

Pleura.—A little to the left of the middle of the tendon of the diaphragm there was a hard grey nodule a quarter of an inch in diameter.

On the pleural surface of the diaphragm, chiefly in the centre and along the margins of the tendon, there were some pale villous-like growths; at the base of some of these minute hard granules could be felt. Of those along the margin of the tendon a few had towards their free ends small tubercles, two of which were reddish, caseous and calcareous.

Similar growths were seen on the pleura covering the last ribs; these growths were very long and slender; one on each side contained at the free extremity a flattened chalky-white body, the size of a wheat grain, almost entirely detached; one such body was found free in the right pleural cavity. On section they were dense, dry and caseous.

Near the apex of the somatic pleura on the left side there was a small grey tubercle.

Lungs.—Scattered evenly throughout the lungs were numbers of hard grey tubercles; they varied in size from a mustard seed to a small pea; all were caseous and softened in the centre; nearly all were appreciably calcified.

The lung tissue between the tubercles appeared to be normal.

Mediastinal and Bronchial Glands.—The mediastinal and bronchial glands were very large. One dorsal mediastinal gland measured 2 in. by 1⅛ in., two behind this were an inch and half an inch in length respectively.

Bronchial Glands.—Each bronchial gland measured 1½ in. by 1 in. by ½ in., and showed areas similar to those described in the iliac glands.

Two glands along the œsophagus, one above the treachea, and a group at the opening of the thorax (above the manubrium sterni) were similarly affected.

Heart and Pericardium.—Normal.

Thymus and Thyroid.—Normal.

Brain and Meninges.—Normal.

Ovaries.—Were cystic; in the tissue between the cysts there were several small greyish points.

Uterus and Fallopian Tubes, Pancreas.—Normal.

Various Lymphatic Glands.

Submaxillary Glands.—The left submaxillary gland was normal; one on the right side was enlarged and tuberculous.

Left Parotid.—Showed a caseous nodule.

Right Parotid, Right and Left Prescapular, Right and Left Cervical, Right and Left Popliteal, Right and Left Lumbar, Right and Left Posterior Pharyngeal.—Normal.

Microscopical Examination (Smear Preparations).

Emulsion of Inguinal Glands.—Twenty-seven tubercle bacilli.
Liver.—No tubercle bacilli.
Lung.—No tubercle bacilli.
Pleura (free body).—No tubercle bacilli.
Spleen.—No tubercle bacilli.
Omentum.—One tubercle bacillus.
Gastric Gland.—No tubercle bacilli.
Mediastinal Gland.—No tubercle bacilli.

Animals Inoculated.

An emulsion was made from the inguinal glands, and inoculated into:—

G. P. 629.	(S.)	Died 69 days.	General tuberculosis.
G. P. 630.	(S.)	Died 67 days.	General tuberculosis.
G. P. 631.	(I.)	Died 19 days.	Tuberculosis.
G. P. 632.	(I.)	Died 29 days.	Tuberculosis.

An emulsion was made from one ovary, and inoculated into:—

G. P. 633. Killed 70 days. No tuberculosis.

PIG 12.

Subcutaneous Inoculation of an emulsion made from the mesenteric glands of Pig 8.

Dose of Emulsion.—10 cubic centimetres. (No tubercle bacilli were found in the emulsion.)

Date.—June 4th, 1903.

Weight.—June 9th, 1903, 1 qr. 10 lbs.

Killed.—October 2nd, 1903, 120 days after inoculation.

Clinical History.

The pig was inoculated subcutaneously on the inside of the left thigh on June 4th, 1903.

A month after inoculation there was a tumour measuring 1½ inches by ¾ inch by about ½ inch, the skin over which was adherent and reddened.

The tumour slowly increased in size, and on August 6th, 1903, 63 days after inoculation, measured 2½ inches by 1½ inch. The tumour then diminished a little and a small ulcer appeared in the skin.

On July 7th, 33 days after inoculation, the glands (three in number) in the groin were enlarged, but separate; they increased in size and became adherent, forming a mass about the size of a small hen's egg.

There was no disturbance of the general health of the animal during the experiment.

Post-Mortem Examination.

The carcass was in good condition; fat everywhere moderately abundant.

At the Seat of Inoculation.—On the inside of the left thigh there was a slightly elevated firm tumour 1¾ in. by 1 in. by ½ in., the skin over it was adherent, dull red, and thinned, and showed at the centre a small ulcer.

On section the tumour consisted of fibrous tissue interspersed with dense chalky white caseous areas. The caseous deposits were more numerous at the periphery of the mass than in the centre. All were gritty from calcification.

In the subcutaneous tissue around the tumour there were perhaps a dozen caseous and calcareous tubercles about the size of wheat grains.

Inguinal Glands.—The glands (five or six in number) in the left inguinal region were enlarged and glued together to form a nodular mass 3 in. by 1 in., weighing one ounce. On section the glands were almost entirely caseous; they were surrounded by thin fibrous capsules, from which they were easily shelled out; the caseous substance was white and dense and gritty from calcification.

One gland in the right inguinal region was slightly enlarged, and showed on section dense greyish-white caseous masses, slightly gritty from calcification; a second gland, not apparently enlarged, contained a small caseous focus; a third gland in this series was normal

A gland at the bifurcation of the aorta was enlarged and infiltrated throughout with caseous gritty areas.

Iliac Glands.—On the left side two were similarly, but not so extensively affected; one right iliac gland, not enlarged, showed a white gritty caseous focus.

Abdomen.

Omentum and Peritoneum.—Normal.

Spleen.—Weighed 2 ounces. Distributed evenly throughout the parenchyma was a number (thirty to forty) of grey tubercles, the size of a large shot; some formed hemispherical projections beneath the capsule; almost all had caseous and calcareous centres.

Liver.—Weighed 1 lb. 12 ozs. On the surface, and uniformly distributed throughout the parenchyma, were numerous greyish tubercles, smaller than those in the spleen; a few only of these showed central caseation. The glands in the hilum were enlarged, and showed similar areas to those described in other glands.

Kidneys.—The left kidney weighed three ounces, and showed beneath the capsule in the cortex two grey translucent tubercles, the size of mustard seeds.

The right kidney weighed three ounces; the cortex contained one tubercle as above.

Suprarenal Bodies.—Normal.

Ovaries.—The size of French beans, were cystic, and showed in the little triangular areas between contiguous cysts a number of grey specks.

Uterus, Fallopian Tubes.—Normal.

Tongue, Pharynx, Larynx, Tonsils.—Normal.

The Glands at the angle of the jaw, parotid and submaxillary, three in number on each side, were firm and enlarged (the largest about the size of a thrush's egg); on section they showed greyish-white translucent areas forming a network throughout the gland tissue; these areas were not softened nor appreciably calcareous, but showed opaque whitish streaks in their centres.

Posterior Pharyngeal Glands, Right Cervical, and Left Prescapular Glands.—Were similarly affected, but not to the same extent.

Left Cervical, Right Prescapular.—Were apparently normal.

The Glands below the trachea, at the opening of the thorax, were enlarged and contained caseating areas.

There was a mass (about the size of a tangerine orange) of enlarged glands between the stomach and the anterior border of the pancreas, which on section were extensively caseated.

The Mesenteric Glands and glands along the whole length of the large intestine, were, without exception, slightly enlarged and showed similar areas of caseation; the areas in the mesenteric glands were more softened than those in other glands.

Lumbar Glands.—Showed a few caseous foci.

Large and Small Intestine.—Normal.

Thorax.

Lungs.—Uniformly scattered throughout normal lung tissue were numerous grey translucent tubercles, of the size of a pin's head; a number were grey and homogeneous throughout, but many showed minute yellow calcareous centres.

Bronchial and Mediastinal Glands.—Were enlarged and showed caseating areas and foci gritty from calcification. The ventral mediastinal glands were similarly affected.

Diaphragm.—The abdominal surface of the diaphragam carried on the central tendon from six to eight prominent rounded hard translucent tubercles, which varied in size from a mustard seed to a wheat grain.

On the pleural surface, there were about half a dozen similar tubercles.

Costal Pleura, Heart, Pericardium.—Normal.

Microscopical Examination (Smear Preparations).

The Emulsion.—Showed tubercle bacilli.
Spleen.—Showed no tubercle bacilli.
Lung.—Showed one tubercle bacillus.
Kidney.—Showed no tubercle bacilli.
Submaxillary Gland.—Showed one tubercle bacillus.
Left Inguinal Gland.—Showed no tubercle bacilli.
Emulsion of Mediastinal Gland, (used to inoculate G.P's.)—Showed one tubercle bacillus.

Paraffin Sections.

Sections through one of the grey tubercles in the kidney showed small cell groups, the central parts of which were necrosed; no giant cells or tubercle bacilli were seen (in four sections).

Sections through one of the ovaries showed clusters of small cells in the position of the grey foci; there was nothing in the arrangement of these to indicate a tuberculous origin or nature (*i.e.*, no giant cells, degeneration or tubercle bacilli).

Animals Inoculated.

An emulsion was made from the inguinal glands, part of the spleen and two hepatic lymphatic glands; the emulsion contained 900 tubercle bacilli per c.c.

Of this Emulsion,

Calf 124, Calf 130, Pig 14, Pig 16, — Each received 10 cc. subcutaneously.
G.P. 602, G.P. 603 — 1 c.c. subcutaneously.
G.P. 605, G.P. 604, — 1 c.c. intraperitoneally.

Emulsion of Mediastinal Gland.

G.P. 606. (Subcutaneously.)

Of the guinea-pigs inoculated with the first emulsion, one died 18 days later and showed only slight tuberculosis; the rest died of general tuberculosis in periods of 60 to 71 days.

Guinea-pig 606 was killed 76 days after inoculation and showed general tuberculosis.

CALF 104.

Subcutaneous.—Inoculation of an emulsion made from the mesenteric glands of Pig 8.

Dose.—10 c.c. (No tubercle bacilli were found).

Date.—June 4th, 1903.

Weight.—June 9th, 1903. 1 cwt.

Killed.—September 11th, 1903. 99 days after inoculation.

Clinical History.

The calf was inoculated subcutaneously on the left side of the neck on June 4th, 1903.

Three weeks after inoculation a small thickening was felt in front of the inferior extremity of the prescapular gland. A week later, this had increased to form a small nodular mass about 1 inch in diameter. Later discrete hard nodules were felt around the mass and a few appeared in the tissues posterior to the gland.

The prescapular gland, three weeks after inoculation, measured 2½ inches by 1½ inch, and at the end of five weeks attained its maximum, 3½ inches by 2½ inches.

The general condition of the calf remained good throughout the experiment.

The temperature rose on the 22nd day to 40·1° C.; it then gradually fell to 39·3° C. on the 25th day, and during the rest of the experiment was practically normal.

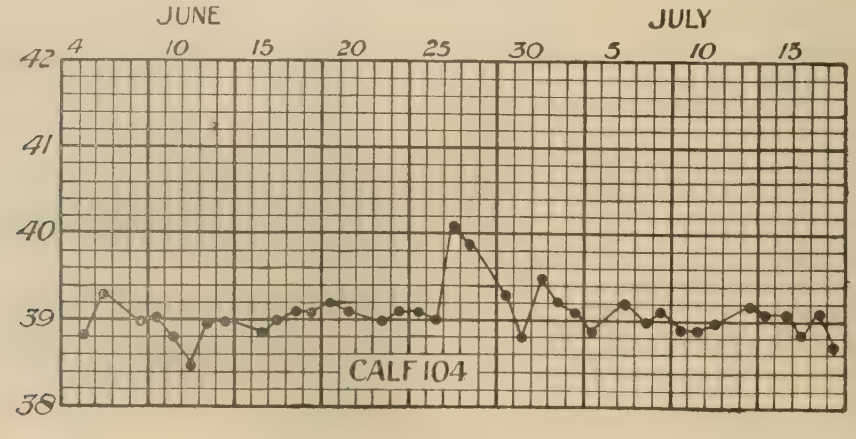
The tuberculin test on September 4th, 1905, 93 days after inoculation, was positive, the temperature rising 2·1° C.

Weights.

During the first seven weeks there was a gain in weight of 52 lbs.; then for a fortnight the weight was stationary; subsequently there was a steady increase in weight.

June 9, 1903 - -	1 cwt.	0 qr.	0 lb.
July 28, 1903 - -	1 cwt.	1 qr.	24 lbs.
August 11, 1903 -	1 cwt.	1 qr.	24 lbs.
September 8, 1903 -	1 cwt.	2 qrs.	10 lbs.
Gain in weight -		2 qrs.	10 lbs.

Temperature.



Post-Mortem Examination.

Carcass.—In moderately good condition.

Local Lesion.—On reflecting the skin from the left side of the neck, numerous yellow hard tubercles were seen in the subcutaneous tissue.

The tubercles lay for the most part anterior to the gland, but there was a small number situated postero-inferiorly. They varied in size from a small shot to a small pea. At one point anterior to the lower end of the gland they formed a nodular mass; elsewhere they were discrete. Some were closely adherent to the skin, others to the aponeurosis of the muscle. On section all had calcareous centres surrounded by pinkish translucent tissue. In the areolar tissue between the superficial and deep muscles, and 2 in. in front of the gland, was a small collection (twelve to fifteen) of similar calcareous tubercles; three others were situated nearer the gland.

The total number of tubercles was not more than 100.

Left Prescapular Gland.—Weighed three ounces, and measured 3 in. × 1¾ in. × 1¼ in. The gland tissue was firm, and the cortex was extensively infiltrated with yellow calcareous particles; near the hilum at the upper end there was an area of caseo-calcareous tissue; the calcareous particles were not so numerous at the lower end of the gland.

Lungs.—Irregularly distributed over the surface, but chiefly on the middle and posterior lobes, were numbers of small tubercles; some were seen just beneath the pleura, others projected. On section they varied in size from a small shot to a large pea and had calcareous centres, and were surrounded by an irregular zone of congestion. On the upper surface of the right lobe there were in addition two pinkish-red flattened tubercles with overhanging edges: the small one (⅛ in. in diameter) had a fringe around its margin, the large one (⅜ in. in diameter) calcareous grains at its base. On each dorsal surface of the posterior lobes there were three similar mushroom like growths, $\frac{5}{10}$ in. in diameter, surrounded by fringes.

On section of the lung, tubercles, the size of a No. 4 shot, were moderately numerous throughout the parenchyma; all were calcareous in the centre. The lung tissue apart from the tubercles was quite normal.

Around the margins of the lungs were delicate fibrinous fringes in which were felt small hard tubercles, grey in colour; delicate fringes were seen on the surfaces of the posterior and middle lobes, arranged along the lines of the interlobular septa.

Pleura.—On the anterior margins of the ribs, chiefly on the right side, were rows of firm pinkish vegetations, in which were, here and there, small hard grey nodules: similar vegetations were seen on the pleura covering the aorta, and a small number occurred at the junction of the muscle and tendon of the diaphragm, and on its central pillars; some of the vegetations on the diaphragm contained yellow caseous tubercles.

Mediastinal Glands.—The dorsal mediastinal glands, four in number, weighed four ounces: they were enlarged, and on section the gland tissue was very congested; in the long posterior gland (4 in. in length) there were numerous calcareous nodules affecting about half the cortex; the remaining three glands were calcareous throughout.

Three small glands along the thoracic trachea contained calcareous nodules.

Bronchial Glands.—Both were enlarged, the left weighing three ounces, and practically completely calcareous.

Heart.—On the left border of the left ventricle there was a prominent white firm oval nodule, the size of a filbert, homogeneous throughout, except for a small lacuna in the centre containing a greenish fluid. Microscopically the tumour was a fibroma.

Intestines.—Normal.

Mesenteric Glands.—Two glands, one at the upper and one at the lower end of the mesentery, each contained a small calcareous nodule.

Colic and Gastric Glands.—Normal.

Spleen.—Weighed nine ounces; on both surfaces there were several small red vascular tufts loosely connected to the capsule. On section there were in all about six shotty tubercles with calcareous centres.

Liver.—On the convex surface of the liver there were from fifteen to twenty small greyish-white tubercles, some just visible through the capsule, others projecting above the surface; also three yellowish white firm growths, from ⅛ to a ¼ in. in diameter, with thin overhanging margins and a slender attachment to the capsule. On the concave surface there were two hemispherical tubercles resembling small pearls.

On section, tubercles the size of a pin's head, calcareous in the centre, were sparsely distributed throughout the liver tissue.

Three Hepatic Lymphatic Glands.—Contained numerous calcareous particles in the cortex, the largest gland being the most affected.

Kidneys.—Each weighed six ounces. Both were normal on the surface and section.

Suprarenals.—Normal.

Tongue, Pharynx, and Tonsils.—Normal

Mammary Gland, Uterus.—Normal.

Various Lymphatic Glands: Left Prepectoral, Right Prepectoral, Right Prescapular, Axillary, Cervical, Submaxillary, Retro-pharyngeal, Lumbar, Iliac, Precrural, Popliteal, Gluteal, Ischial, Supramammary.—Normal.

Microscopical Examination (Smear Preparations).

Local Tumour.—No tubercle bacilli.

Left Prescapular Gland (Emulsion).—Tubercle bacilli.

Mesenteric Gland.—Tubercle bacilli.

Liver.—Tubercle bacilli.

Lung.—A few tubercle bacilli.

Spleen (Emulsion).—One tubercle bacillus.

Nodule on Diaphragm.—Two or three tubercle bacilli.

Animals Inoculated:—

With Emulsion of Left Prescapular Gland:

G. P. 562.—(S.) Died in 29 days of general tuberculosis.

G. P. 563.—(S.) Died in 38 days of general tuberculosis.

G. P. 564.—(I.) Died in 20 days of general tuberculosis.

G. P. 565.—(I.) Died in 29 days of general tuberculosis.

With Emulsion of Spleen (two tubercles):

G. P. 566.—(S.) Died in 39 days of general tuberculosis.

CALF 106.

Subcutaneous Inoculation of an emulsion made from the mesenteric glands of Pig 8.

Dose.—10 cubic centimetres. (No tubercle bacilli were found in the emulsion).

Date.—June 4th, 1903.

Weight.—June 9th, 1903. 1 cwt., 0 qr., 21 lbs.

Killed.—September 12th, 1903. 100 days after inoculation.

Clinical History.

The calf was inoculated subcutaneously on the left side of the neck on June 4, 1903.

Three weeks after inoculation a small irregular mass was felt at the lower extremity of the left prescapular gland. This increased in size a little and became very hard and nodular, and discrete nodules were felt in the subcutaneous tissues over the gland and along its posterior margin.

The prescapular gland, three weeks after inoculation, measured 2½ in. by 1½ in.; it slowly enlarged and at the end of seven weeks measured nearly 4 in. in length; it then underwent a slight diminution in size.

The general health of the calf remained good throughout the experiment.

The temperature rose sharply to 40·4°C. on the 22nd day and then gradually fell to the normal on the 25th; during the rest of the experiment the temperature was normal.

Tuberculin Tests.—September 4, 1903, 92 days after inoculation. Positive. Rise of temperature 2·3°C

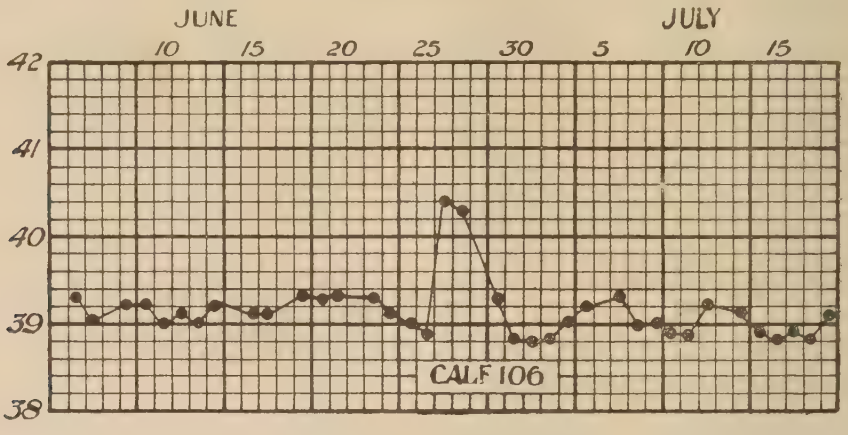
September 11, 1903, 99 days after inoculation. Positive. Rise of temperature 1·5°C.

Weights.

The weight steadily increased.

June 9, 1903.—1 cwt. 0 qr. 21 lbs.
September 8, 1903.—2 cwt. 0 qr. 4 lbs.
Gain in weight, 3 qrs. 11 lbs.
Rate of gain per week, 7·3 lbs.

Temperature.



Post-Mortem Examination.

Carcass in very good condition.

Local Lesion.—In the subcutaneous tissue immediately over that part of the sterno-mastoid muscle which covered the left prescapular gland were five yellow tubercles, varying in size from a small shot to a large pea; on section they had calcareous centres surrounded by pinkish translucent tissue.

In the loose tissue around the lower end of the left prescapular gland was a collection of similar yellow tubercles, numbering about 100. The tubercles were grouped chiefly around the inferior extremity of the gland, but they also extended half way up the posterior margin and slightly along the anterior; in the latter situations they were discrete and varied in size as above; in the former they formed nodular masses; all on section were calcareous in the centre.

Left Prescapular Gland.—Weighed 3 ounces and measured 3 in. by 1¾ in. On section the upper two-thirds of the cortex of the gland contained large caseo-calcareous masses; the lower third discrete calcareous particles.

Right Prescapular Gland.—Weighed a little over 1 ounce and measured 2½ in. by 1¼ in.; the tissue was œdematous, but there were no hæmorrhages.

At the seat of inoculation of the tuberculin on the right side there was a fairly well defined œdematous swelling. 5 in. by 3½ in. On section through the swelling the œdema was seen to infiltrate the underlying muscle, and to extend into the deep areolar tissue.

Thorax.

Lungs.—Normal on surface and on section.

Mediastinal Glands.—In the cortex of the long dorsal mediastinal gland there was a small yellow calcareous tubercle.

Other mediastinal and the bronchial glands were normal.

Pleura and diaphragm, normal.

Abdomen.

Omentum and Peritoneum.—Normal.

Spleen (9¾ ozs.).—Showed on both surfaces a few very small vascular tufts loosely attached to the capsule: on section normal.

Liver.—Normal.

Hepatic Lymphatic Glands.—Normal.

Kidneys and Suprarenal Bodies.—Normal.

Tongue, Tonsils, Pharynx
Intestines, Mammary Glands } Normal.

Other Lymphatic Glands.

Submaxillary, Posterior Pharyngeal, Cervical, Right and Left Prepectoral, Right and Left Axillary, Precrural, Popliteal, Gluteal, Ischiatic, Iliac, Lumbar, Gastric, Colic and Mesenteric Glands.—Normal.

Microscopical Examination (Smear Preparations).

Left Prescapular Gland.—Numerous T.B.
Tubercle from Local Lesion.—A few T.B.
Nodule from Mediastinal Gland.—No T.B.

Animals Inoculated.

With Emulsion from Left Prescapular Gland:—

G.P. 567. (S.) Died in 69 days of general tuberculosis.
G.P. 568. (S.) Died in 41 days of general tuberculosis.
G.P. 569. (I.) Died in 28 days of general tuberculosis.
G.P. 570. (I.) Died in 29 days of general tuberculosis.

With Emulsion from Spleen:—

G.P. 571. (S.) Died in 69 days of general tuberculosis.

PIG 14.

Subcutaneous Inoculation of an emulsion made from the inguinal glands, two hepatic lymphatic glands and part of the spleen of Pig 12.

Dose of Emulsion.—10 c.c., containing about 9,000 tubercle bacilli.

Date.—October 2nd, 1903.

Weight.—October 6th, 1903. 1 cwt., 0 qr., 25 lbs.

Killed.—January 25th, 1904. 115 days after inoculation.

Clinical History.

The pig was inoculated subcutaneously on the inside of the left thigh on October 2, 1903.

A fortnight after inoculation there was a tumour the size of a filbert, the skin over which was adherent; the inguinal glands were a little enlarged. Forty days after inoculation the tumour measured 3 in. by 1½ in. by about 1 in.; the skin was thoroughly adherent, dull red and scaly; in the groin there was a mass of enlarged glands.

On December 9th the centre of the tumour was felt to be softened and the skin in the centre was depressed, thinned, and showed some adherent scabs. Thickened

lymphatic vessels stretched between the tumour and the mass of enlarged glands in the groin. Subsequently the tumour ulcerated and diminished somewhat in size.

No signs of ill-health were observed during the experiment; the appetite remained good, and there was a gain in weight; the pig, however, was not so fat, and did not grow at the same rate, as two control pigs belonging to the same litter.

The temperature rose on the 7th day to 39·5°C., and fell to the normal on the next day; it rose again on the 18th day and was high for three days (maximum 39·9°C.); subsequently, except for two slight rises, one to 39·3°C., the temperature was normal.

Weights.

During the first four weeks there was a steady gain in weight, amounting altogether to 31 lbs.; during the remainder of the experiment the weight fluctuated between 1 cwt. 1 qr. 14 lbs. and 1 cwt. 2 qrs. 15 lbs.

October 6th, 1903 -	1 cwt.	0 qrs.	25 lbs.
November 3rd, 1903	1 cwt.	2 qrs.	0 lbs.
December 1st, 1903	1 cwt.	1 qr.	14 lbs.
December 22nd, 1903	1 cwt.	2 qrs.	15 lbs.
January 19th, 1904	1 cwt.	2 qrs.	9 lbs.
Gain in weight-		1 qr.	12 lbs.

Post-Mortem Examination.

Condition.—Moderate.

At the Seat of Inoculation.—On the inside of the left thigh, there was a ridge 3 inches long, ¾ inch broad, and about ¾ inch high. In the centre of this ridge there was a narrow shallow ulcer, with puckered margins, a little over 1 inch long; the ulcer at the anterior end discharged thick yellow pus, but elsewhere was cicatrised.

When cut into the ridge was found to be composed of fibroid tissue containing, principally in the deeper parts, scattered caseous and softened tubercles.

In the subcutaneous tissue adherent to this ridge there were a few discrete yellow tubercles, appreciably gritty.

Between the local lesion and the inguinal glands there was a slightly thickened lymphatic vessel, which showed here and there along its course caseous nodules; the lumen of the vessel was patent.

Inguinal Glands.—The superficial inguinal glands were enlarged, and fused together to form a mass 3 inches by 1½ inches by 3 inches, weighing 2 ounces. On section all the glands were caseous throughout, with the exception of one or two small glands at the margin of the mass, which contained discrete yellow foci; the caseous areas were appreciably gritty.

The superficial inguinal glands on the right side were normal in size and appearance.

Iliac Glands.—The iliac glands on the left side (five in number) were enlarged and indurated; the posterior one of the series, the size of a chestnut, was entirely caseous; the four glands anterior to this, and a quarter the size, were beset with caseous foci.

The iliac glands on the right side were slightly indurated but were otherwise normal.

Lumbar Glands.—Normal.

Abdomen.

Omentum, Peritoneum.—Normal.

Spleen.—Weighed 4 ounces, and showed no sign of tubercle either on the surface or on section.

Liver.—Showed on the surface beneath the capsule half-a-dozen minute whitish foci; in the depth of the liver substance there was a minute yellow focus with a gritty centre.

Kidneys.—The right kidney contained in the cortex, near the surface, a grey translucent point, just visible to the naked eye. Left kidney normal.

Suprarenals.—Both normal.

Gastric Glands.—On the posterior wall of the stomach, near the lesser curvature, and beneath the peritoneum, there was a group of glands, one of which contained a caseous, slightly calcareous nodule. One or two glands similarly placed, but on the anterior wall, were normal.

Portal Glands.—In the interval between the pancreas and the hilum of the liver there were four or five enlarged and indurated glands, which on section showed numerous caseous gritty foci.

Mesenteric Glands, Colic Glands.—Normal in size, showed no visible tubercles.

Small Intestine, Large Intestine.—Normal.

Thorax.

Lungs.—Contained a number (about thirty were counted in each lung) of caseous tubercles, ranging in size from a mustard seed to a large shot; the tubercles were softened in the centre, and the larger ones had distinct fibrous capsules.

Bronchial Glands.—On the left side were considerably enlarged, and closely beset with caseous tubercles.

The glands on the right side were only slightly enlarged, but contained similar caseous foci.

The glands in the dorsal mediastinum appeared normal.

Pleura (Parietal and Visceral), Heart, Pericardium.—Normal.

Larynx and Trachea.—Normal.

Right and Left Cervical (Superficial and Deep), Right and Left Prescapular Glands.—Normal.

Right and Left Prepectoral, Right and Left Precrural Glands.—Normal.

Post-Pharyngeal Glands, Submaxillary Glands.—Normal.

Testicles.—Both testicles, and the peritoneum covering them, were normal.

Over the site of the inoculation of the tuberculin (inside of right thigh) there was an area of desquamation of the superficial epithelium.

Microscopical Examination (Smear Preparations).

Left Inguinal Glands (Emulsion).—Two tubercle bacilli.

Liver.—No tubercle bacilli.

Lung.—No tubercle bacilli.

Guinea-Pigs Inoculated.

Guinea-pig 826 was inoculated subcutaneously with an emulsion from the spleen; it was killed after 97 days and found to be free from tuberculosis.

Guinea-pig 827, inoculated subcutaneously with an emulsion made from the liver, died in 95 days of general tuberculosis.

Guinea-pig 829, inoculated intraperitoneally with an emulsion from an inguinal gland, died in 34 days of general tuberculosis.

PIG 16.

Subcutaneous Inoculation of an emulsion made from the left inguinal glands, two hepatic glands and part of the spleen of Pig 12.

Dose of Emulsion.—10 c.c., containing about 9,000 tubercle bacilli.

Date.—October 2nd, 1903.

Killed.—January 16th, 1904. 105 days after inoculation.

Clinical History.

The pig was inoculated subcutaneously on the inside of the left thigh on October 2nd, 1903.

A fortnight after inoculation there was a tumour adherent to the skin, about the size of a filbert; the glands in the groin were a little enlarged.

Sixty-eight days after inoculation the tumour measured 5 in. by 2 in., and thickened lymphatic vessels were felt between it and the mass of enlarged glands in the groin; the skin over the centre of the tumour showed a few dry scabs.

The tumour then diminished a little in size and the

skin in the centre became depressed, thinned and finally ulcerated.

The general condition of the animal remained good throughout the experiment.

The temperature rose on the seventh day to 39·6° C., and during the first month there was slight irregular pyrexia (maximum 39·4°C.); subsequently, except for one or two slight rises, the temperature was normal.

Weights.

October 6th, 1903 -	- 1 cwt.	0 qrs.	7 lbs.
January 12th, 1904	- 1 cwt.	1 qrs.	24 lbs.
Gain in weight -	-	1 qr	17 lbs.

Post-Mortem Examination.

Condition.—Moderate.

Local Lesion.—Extending across the surface of the left thigh at the seat of inoculation there was a ridge about 4½ in. in length, and about ¾ in. in width at the widest part. At the base of the ridge, on its lower side, there was a narrow ulcer over an inch in length.

On dissection this ridge was found to be mainly composed of an aggregation of tubercles, mostly with yellow caseous centres. The skin was partially adherent to the mass.

Leading forwards from this lesion to the superficial inguinal glands on the same side there was a number of lymphatic vessels of the diameter of a goose quill. On section these were found to have no distinct lumen, and were almost entirely caseous.

Inguinal Glands.—The left superficial group of inguinal glands formed a single mass weighing 3½ ozs., and measuring 3½ in. by 2 in. by 1¼ in. On section the glands were necrotic and caseous throughout. The caseous tissue was firm, and was readily shelled out from the surrounding gland capsules.

On the right side the inguinal glands were of about normal size, but slightly indurated, and showed one or two points of caseation.

Iliac Glands.—On the left side the iliac glands were enlarged to three or four times the normal size, and were closely beset with caseous tubercles.

Both iliac and superficial inguinal glands were just perceptibly calcified.

Right iliac glands normal in size and appearance.

Lumbar Glands.—Normal in size and appearance.

Abdomen.

Omentum.—Normal.

Peritoneum.—The peritoneum covering the diaphragm on the right side showed two clusters of tubercles; there were also two or three tubercles on the peritoneum covering the right crus of the diaphragm (the tubercles on the tendon of the diaphragm caused subpleural as well as subperitoneal elevations); elsewhere the peritoneum, both parietal and visceral, appeared normal.

Spleen.—The spleen was of normal size, but in its substance there were about a dozen tubercles, the largest being about the size of a pea; these were caseous centrally, and had distinct fibrous capsules.

The Liver contained numerous tubercles underneath the peritoneum, also throughout the substance; these were about the size of pin-heads.

Kidneys and Suprarenal Bodies.—Normal.

Gastric Glands.—The gastric group of glands was enlarged, and almost completely destroyed by caseation.

Stomach.—Normal.

Intestines.—Several Peyer's patches showed suspicious opacity of their lymphoid tissues (a smear preparation was made from one of the patches, but no tubercle bacilli were found). Otherwise normal.

Large Intestine.—Normal.

Mesenteric Lymphatic Glands, Colic Lymphatic Glands were normal in size, and showed no visible lesions.

Tongue, Throat, Tonsils, Post-Pharyngeal Lymphatic Glands, Submaxillary Glands.—Normal.

Thorax.

Lungs.—Both lungs contained numerous tubercles (some hundreds), mostly about the size of barley grains or smaller; these had distinctly caseous centres.

The Bronchial Glands on both sides were enlarged, and closely beset with caseous tubercles.

Pleura.—Several yellow tubercles about the size of barley grains were present in the mediastinal pleura behind the heart, and also in the special fold of pleura surrounding the vena cava.

On each side of the chest wall, under the pleura covering an intercostal space, there was a single tubercle.

Pericardium, Heart Muscle and Valves.—Normal.

Thymus.—Normal.

Cervical Glands, Prescapular and Prepectoral.—Normal on both sides.

Right Popliteal.—Normal.

Testicles.—Under the peritoneum covering the left spermatic cord and epididymis there were about half a dozen firm tubercles, the largest about the size of a barley grain. The testicle itself, and the substance of the epididymis, appeared normal.

Bladder.—Normal.

Microscopical Examination (Smear Preparations).

Emulsion of Inguinal Glands.—Tubercle bacilli (not numerous).

Liver.—No tubercle bacilli.

Spleen.—Tubercle bacilli (scanty).

Intestine (Peyer's Patch) } No tubercle bacilli.
Lung. }

Animals Inoculated.
With Emulsions.

Four guinea-pigs were inoculated, two subcutaneously, and two intraperitoneally, with an emulsion made from the left inguinal glands; all died of general tuberculosis in periods varying from 24 to 56 days.

With Culture.

A culture was obtained from an inguinal gland and inoculated into two rabbits (*see* below), two pigs, and a calf.

Rabbits.

No. of Rabbit.	Initial Weight in grammes.	Final Weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
159	1,700	1,200	1·0 mg.	Intravenous	Died, 21 days	General tuberculosis.
158	1,000	1,070	1·0 mg.	Intraperitoneal	Died, 62 days	General tuberculosis; the inoculation was partly subcutaneous.

CALF 124.

Subcutaneous Inoculation of an emulsion made from the inguinal and hepatic lymphatic glands and the spleen of Pig 12.

Dose.—10 cubic centimetres, containing approximately 9,000 tubercle bacilli.

Date.—October 2, 1903.

Weight.—1 cwt.

Died.—December 12, 1903, 71 days after inoculation.

Clinical History.

The calf was inoculated subcutaneously on the left side of the neck on October 2nd, 1903.

A fortnight after inoculation there was a small local thickening. At the end of the third week there was a tumour measuring 3½ in. by 2½ in. by about 1 in.; this slowly increased in size, and at the end of the 8th week measured 5 in. by 3 in.

The left prescapular gland at the end of a fortnight was slightly enlarged, and on November 20th, seven weeks after inoculation, measured nearly 5 in. in length.

The calf was first noticed to be ill about seven weeks after inoculation; the coat was staring and there was some loss of appetite. On November 28th, 57 days after inoculation there was slight diarrhœa, and on November 30th, the respirations were visibly increased. These symptoms increased in severity; diarrhœa became more marked: the respirations were rapid and laboured, expiration ending audibly; the appetite was poor and there were progressive emaciation and weakness.

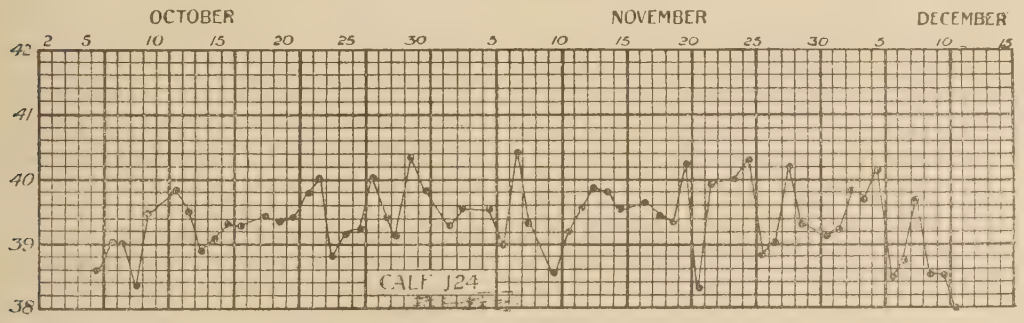
On the day before death the calf was very weak and emaciated and almost unable to stand; the head was outstretched, and respiration was very laboured.

Weights.

During the first month there was a gain in weight of 15lbs., then there was a gradual decline.

October 6th, 1903 -	1 cwt.	0 qr.	0 lb.
November 3rd, 1903 -	1 cwt.	0 qr.	15 lbs.
December 8th, 1903 -	0 cwt.	3 qrs.	22 lbs.
Loss in weight - - - -			6 lbs.

Temperature.



Post-Mortem Examination.

Carcass.—Very emaciated.

At the Seat of Inoculation.—On the left side of the neck, in the subcutaneous tissues, there was a rounded prominent tumour 4 in. by 2 in. by 1½ in. The skin over it was thoroughly adherent, but not ulcerated. On section the tumour was entirely composed of a congested, firm yellowish white tissue, dotted here and there with minute opaque yellow calcareous particles; the peripheral parts of the mass were broken up into nodules surrounded by hyperæmic fibrous tissue. At the inferior extremity of the tumour, and partly covered by it, there was a mass (2 in. by 1 in.) of caseous, slightly gritty tubercles, surrounded by firm tissue. A thickened tortuous caseous lymphatic vessel could be traced from the tumour to the left prescapular gland.

The tissues around the local tumour and the neighbouring glands were œdematous and congested.

Left Prescapular Gland.—Weighed 5 ozs., and measured 4 in. by 2 in. by 1⅛ in. On section it was caseous throughout and slightly gritty.

Prepectoral Glands.—A left prepectoral gland, the size of a small walnut, was deeply congested, and showed in the cortex a caseous mass affecting about one-third of the gland substance; in the less affected portion minute grey foci were seen. A second and deeper prepectoral gland was a little enlarged and showed one greyish focus. A third was not obviously affected.

Cervical Glands.—Two glands on the left side of the trachea, about midway, the size of broad beans, were caseous throughout. A corresponding gland on the opposite side was normal.

A gland a little anterior to the former, and slightly smaller, was slightly affected.

A gland about the level of the larynx, twice the size of a broad bean, was also tuberculous throughout.

Two small glands on the same side of the trachea (left), near the anterior opening of the thorax, were tuberculous; one showed a mass which occupied more than half the cortex, the other minute greyish-yellow foci.

Abdomen.

Omentum.—Free from fat. Showed on the inferior surface about a dozen tubercles, 1 to 2 mm. in diameter, a few of which were deeply congested; the surface in contact with the stomach and intestines was normal.

The peritoneal cavity contained about 6 ozs. of blood-stained fluid.

Spleen.—Weighed 4½ ozs. On the convex surface there was a firm flattened nodulated growth 7 mm. in diameter. On section the pulp was filled with nodules from 1 to 7 or 8 mm. in diameter. All the nodules were caseous in the centre, greyish around the margins: several contained calcareous grains.

Liver.—Weighed 4½ lbs. On both surfaces there was a considerable number of pearly nodules, ranging in size from 1 cm. downwards. On the convex surface the larger projecting nodules were flattened and had slightly overhanging margins; on the concave surface they were rounded. On section through the liver tubercles were moderately numerous in every part; these rarely exceeded 5 mm. in diameter. All the growths exhibited central caseation; a few only contained calcareous grains.

Hepatic Lymphatic Glands (four in number).—Two large, with nodular surfaces, and two small, weighed together 2½ ozs., and consisted throughout of masses and nodules of caseous, slightly gritty tuberculous tissue.

Kidneys.—The left weighed 9 ozs. and showed in the cortex near the surface twelve to fifteen slightly caseous tubercles ranging in size from a mustard seed to a good-sized shot. The tubercles appeared on the surface, but did not project. In the deeper parts of the cortex similar tubercles were seen, but these were few in number. In addition to the above there were three wedge-shaped areas occupying the whole thickness of the cortex, and projecting slightly above the surface, the largest being 1 cm. long by 0·5 cm. broad; these appeared to be formed of a number of small tubercles which had coalesced.

The right kidney (10 ozs.) showed similar, but less numerous tubercles, and two small wedge-shaped areas; the contiguous halves of two lobules in this kidney were grey in colour and anæmic.

Suprarenal Bodies.—The right contained in the medulla a grey tubercle the size of a pin's head; tubercle bacilli were found in a smear prepared from this. The left was normal.

Small Intestine.—Congested in parts (? hypostatic); no tubercles found.

Large Intestine.—No tubercles found.

Gastric Glands.—One gastric gland contained a caseating nodule 5 mm. in diameter. Two others showed minute foci.

Mesenteric Glands.—All the mesenteric glands, with about four exceptions, these being chiefly towards the posterior end, contained caseating nodules ranging in size from a small seed to a small pea.

Thorax.

Lungs.—With the thoracic glands attached, weighed 9 lbs. 4 ozs. The anterior lobes and anterior portions of the posterior lobes were completely consolidated, deeply congested and oedematous. The portions of the posterior lobes not entirely solid showed patches of consolidation alternating with oedematous and congested crepitant lung tissue.

The tissue of the lung was packed with tubercles and nodules ranging in size from 1 mm. or less up to 1 cm. in diameter. Those on the surface of the anterior lobes and the ventral surfaces of the posterior lobes formed greyish white projections, the majority rounded, but a few flattened and mushroomed. On section the nodules were grey and translucent, and contained centrally a caseous focus, in many cases gritty; the nodules had an irregular outline, and in several places had become confluent.

The fringes around the margins of the lungs were not hypertrophied, but showed at wide intervals a few small hard tubercles.

On the costal pleura, along the margins of the ribs, there were on each side from fifteen to twenty caseous tubercles 1 to 3 mm. in diameter; they occurred singly and in clusters of three and four.

Mediastinal Glands.—In the dorsal mediastinum there was a chain of large glands, seven in number, weighing together 9 ozs., the long posterior gland alone weighed ·6 ozs. and measured 5½ in. by 1¾ in. by 1½ in. On section the glands were tuberculous throughout and slightly gritty; the two glands in the anterior part of the mediastinum showed more advanced caseation than those in the posterior.

Bronchial Glands.—The left bronchial gland weighed 1½ ozs., the right about 1 oz.; both were caseous throughout.

A small gland in front of the right bronchial, the size of a French bean, was congested and showed a few grey foci.

Two peribronchial glands on the right side, the size of walnuts, were entirely caseous.

A small gland on the oesophagus contained a pea-sized caseous nodule; a second one showed minute grey foci.

The ventral mediastinal glands were slightly enlarged but not apparently tuberculous.

A gland in the caval fold of the pleura contained a caseous nodule the size of a large pea; a second gland in the same fold, but nearer the centre of the tendon, contained a nodule half the above size.

Diaphragm.—On the pleural surface of the diaphragm, on the left side, there was a group of four small caseous tubercles. Around the margins of the tendon there were a few delicate, very vascular outgrowths.

On the abdominal surface, dorsally on the right side, there were from fifteen to twenty flattened subperitoneal tubercles, about the size of wheat grains.

Pericardium.—The external surface presented some intensely red velvety granulations, and a number of small greyish-yellow tubercles.

The internal surface was normal.

The pericardial sac contained a small amount of yellow fluid.

Heart Muscle and Valves.—Normal.

Pancreas, Thymus, Thyroid, Tongue, Pharynx, Larynx, Tonsils.—Normal.

Various Lymphatic Glands.—Along the whole length of the abdominal aorta there was a chain of glands, eight to ten in number, ranging in size from a broad bean up to 2 in. in length. On section they all contained confluent caseous masses; in the case of the smaller glands replacing the whole of the gland tissue.

Iliac Glands.—A left iliac gland showed in the cortex two caseous nodules, 4 mm. in diameter; two small glands near this were not obviously affected.

A right iliac gland contained a caseous nodule 5 mm. in diameter.

A gland at the bifurcation of the aorta contained a similar nodule.

Right Submaxillary.—Contained a caseous tubercle the size of a No. 4 shot.

Right and Left Axillary, Right Prescapular, Right and Left Prepectoral, Right and Left Precrural, Right and Left Popliteal, Right and Left Gluteal, Right and Left Ischiatic, Right and Left Parotid, Right and Left Posterior Pharyngeal, Left Submaxillary, Vertebral.—Normal in size; no tubercle.

Microscopical Examination (Smear Preparations).

Prescapular Gland (Emulsion), *Right Suprarenal Body* } Tubercle bacilli.

Animals Inoculated.

With Emulsion of Prescapular Gland:—

G.P. 749. (S.), G.P. 750. (S.) } died in 37 days of general tuberculosis

G.P. 751. (I.) died in 21 days, G.P. 752. (I.) died in 20 days } of general tuberculosis.

CALF 130.

Subcutaneous.— Inoculation of an emulsion made from the inguinal and hepatic lymphatic glands and the spleen of Pig 12.

Dose.—10 cubic centimetres, containing approximately 9,000 tubercle bacilli.

Date.—October 2, 1903.

Weight.—October 6, 1903. 3 qrs. 8 lbs.

Killed.—January 15, 1904. 105 days after inoculation.

Clinical History.

The calf was inoculated subcutaneously on the left side of the neck on October 2nd, 1902.

A fortnight later there was a small patch of thickening at the seat of inoculation and the left prescapular gland was about twice the normal in size.

Three weeks after inoculation there was a flat swelling 3½ in. by 2 in., adherent to the skin ; the prescapular gland measured 2½ in. in length.

Seven weeks after inoculation the tumour measured 4 in. by 2½ in. and the prescapular gland about 3 in. in length. Subsequently there was little change in the local conditions. The calf remained in good health during the experiment and gained in weight.

Tuberculin Tests.—January 6th, 1904, 96 days after inoculation. Positive. Rise of temperature 1·1° C.

January 13th, 1904, 103 days after inoculation. Positive. Rise of temperature 1·0° C.

Temperature.

Twelve days after inoculation the temperature rose to 39·8° C., the highest point reached during the experiment. Subsequently it remained very constant, varying only between 39·1 and 39·5° C.

Weights.

The calf was weighed every week and showed an almost steady uniform increase in weight.

October 6th, 1903 -	- 0 cwt. 3 qrs. 8 lbs.
January 12th, 1904 -	- 1 cwt. 1 qr. 26 lbs.
Gain in weight - -	- 2 qrs. 18 lbs.
Rate of gain per week	- 5·25 lbs.

Post-Mortem Examination.

Carcass.—Condition fair.

At the Seat of Inoculation.—On the left side of the neck there was a firm nodular thickening, 3 in. by 2½ in. ; when removed and cut into the tumour was seen to be from ½ to ¾ inch thick, and to consist of closely packed nodules 2 to 4 mm. in diameter, surrounded by fibroid tissue. The nodules were yellow in colour, and appreciably calcified ; they were for the most part separate, and some had coalesced to form large masses. The skin was adherent, but not ulcerated or infiltrated.

The growth was fixed to the aponeurosis of the superficial muscles. The muscles showed three small groups of nodules continuous with the main mass ; one proceeded from the anterior extremity, one from the posterior, and one from the under surface ; with the exception of these the tumour was wholly subcutaneous.

In the subcutaneous tissues over the inferior extremity of the prescapular gland there were two or three isolated calcareous tubercles ; similar tubercles occurred at the extremity of the gland, embedded in the muscle and fat ; calcareous tubercles, some subcutaneous, others intramuscular, were seen between the tumour and the mid line of the neck.

Left Prescapular Gland.—Weighed about an ounce, and measured 2½ in. by 1½ in. by ¾ in. On section it showed in the midst of the gland substance an oval mass (1 in. by ¾ in) which consisted of firm caseous tissue, slightly gritty in the central part, highly calcareous around the periphery ; in the cortex there were scattered calcareous nodules showing little caseous tissue. The lower part of the gland showed two similar nodules (the size of a pea) and minute scattered calcareous grains ; with these exceptions, this part of the gland had a normal appearance.

Prepectoral Glands (on left side).—The most superficial gland, the size of a walnut, showed beneath the capsule numerous elevated yellow nodules. On section it consisted throughout of firm caseating tissue, perceptibly gritty. A second gland, more deeply situated, and about half the size, contained a few yellow gritty foci—otherwise normal.

Cervical Glands.—A lower cervical gland on the left side, an inch in front of the manubrium sterni, showed caseous foci. A middle cervical gland on the same side showed similar foci.

Upper Cervical Glands.—Normal.

Right Middle and Lower Cervical Glands.—Normal.

Right and Left Axillary Glands.—Normal.

Right Prescapular Gland was enlarged, measuring 3 in. by 1¼ in. by ½ in. ; on section soft and œdematous, with a patch of congestion (tuberculin test 41 hours previously) ; The subcutaneous tissues and muscles at seat of inoculation of tuberculin were slightly œdematous.

Right Prepectoral Glands.—Normal.

Abdomen.

Omentum.—Moderately fatty ; free from tubercles.

Peritoneum.—Everywhere normal.

Spleen.—Weighed 6 ozs. Normal on the surface ; contained in the pulp about a dozen yellow tubercles from 2 to 3 mm. in diameter ; the larger nodules only showed caseous and gritty foci centrally.

Liver.—Weighed 3 lbs. 6 ozs. On the anterior surface, beneath the capsule, but embedded in the parenchyma, there were two yellow nodules, one 2 mm., the other 4 mm. in diameter. The former was not caseous, the latter projected slightly, had a flattened surface, and was caseous in the centre.

On section the liver appeared normal throughout.

Hepatic Lymphatic Glands (three in number).—Two normal ; one contained a few calcareous grains.

Gall Bladder.—Normal.

Kidneys.—Each weighed 6 ozs. Both normal.

Suprarenal Bodies.—Normal.

Pancreas.—Normal.

Two glands between the stomach and the left pillar of the diaphragm were normal.

Gastric Glands, Mesenteric, Colic.—Normal.

Small Intestine, Large Intestine.—Normal throughout.

Tongue, Pharynx, Tonsils, Œsophagus, Posterior Pharyngeal Glands, Submaxillary, Parotid, Mastoid Glands.—On both sides normal.

Thorax.

Pericardium.—Contained a small amount of clear fluid.

Heart Muscle and Valves.—Normal.

Lungs.—Right cephalic lobe, normal.

Left cephalic lobe showed on the superior surface two soft vascular fibrous tufts, and in the substance beneath the pleura one grey translucent tubercle 2 mm. in diameter, and two or three minute grey points.

Left caudal lobe carried on the mediastinal surface a mushroomed nodule 4 mm. in diameter ; on this surface there were seen beneath the pleura two minute tubercles similar to those in the cephalic lobe.

On the superior surface of the right caudal lobe there was a small mushroomed growth; at the posterior margin of the lobe there was a firm nodule, 1 cm. in diameter, which occupied part of a lobule, and showed on section yellow foci; loosely attached to the free edge of this lobule there was a pinkish, fleshy fringe. Beneath the pleura in other parts of the lobe there were three caseous and gritty tubercles, 1 to 3 mm. in diameter; on section a similar tubercle was found in the substance.

The lung tissue, apart from the above-mentioned bodies, had a perfectly normal appearance.

Dorsal Mediastinal Glands.—The long caudal gland, not obviously enlarged, showed in the cortex here and there groups of yellow gritty foci. The two glands anterior to this showed scattered calcareous grains.

Left Bronchial Gland.—Not enlarged; contained a few groups of yellow gritty foci.

Right Bronchial Glands (two in number) were similarly affected.

Peribronchial Glands (on each side) also showed calcareous foci.

Ventral Mediastinal Glands.—Normal.

The glands just within the anterior opening of the thorax were normal.

Parietal pleura and parietal surface of diaphragm normal.

Larynx, Trachea, Mammary Gland, Supramammary Lymphatic Glands, Iliac Glands, Sacro-Iliac Glands, Lumbar Glands, Precrural Glands, Popliteal Glands, Gluteal Glands, Ischiatic Glands, Ovaries, Uterus, Fallopian Tubes, Thymus, Thyroid.—Normal.

Microscopical Examination.

Smears from:—

Prescapular Gland.—Tubercle bacilli.

Liver.—A few tubercle bacilli.

Spleen.—No tubercle bacilli.

Spleen.—No tubercle bacilli.

Animals Inoculated:—

An emulsion was prepared from the prescapular gland, and equal quantities inoculated into Guinea pigs 796 and 797 subcutaneously and 798 and 799 intraperitoneally; all died tuberculous in periods varying from 22 to 44 days.

PIG 98.

Subcutaneous.—Inoculation of culture from Pig 16.

Dose.—1·0 milligramme.

Date.—January 10, 1905.

Weight.—January 17, 1905. 1 qr. 16 lbs.

Died.—March 29, 1905, 78 days after inoculation.

Clinical History.

The pig was inoculated subcutaneously in the wall of the abdomen on January 10, 1905.

Three weeks after inoculation there was a flat tumour 1 in. in greatest diameter; the right inguinal glands were moderately enlarged. Subsequently the local conditions showed very little alteration.

The animal was first noticed to be ill on March 1, 50 days after inoculation; the back was arched, the skin tight and wrinkled and the appetite poor. These signs continued and the animal got gradually worse; towards the end the respirations were visibly increased.

The temperature rose on the 9th day to 39·5° C.; with this exception the temperature was practically normal throughout.

Weights.

During the first three weeks there was a loss in weight of 2 lbs. then the weight steadily increased.

January 17, 1905	-	-	- 1 qr. 16 lbs.
February 7, 1905	-	-	- 1 qr. 14 lbs.
February 21, 1905	-	-	- 1 qr. 20 lbs.
March 7, 1905	-	-	- 1 qr. 24 lbs.
March 14, 1905	-	-	- 2 qrs. 0 lb.
March 28, 1905	-	-	- 2 qrs. 7 lbs.

Gain in weight, 19 lbs.

Post-Mortem Examination.

Carcass in very poor condition.

The Local Lesion was situated in the muscles on the right side of the abdomen a little anterior to the umbilicus; it was small and flat, measuring 1 in. by ¾ in. by ¼ in. and consisted of tough, waxy white caseous tissue interspersed with fine opaque white streaks of beginning calcification; the skin was slightly adherent at one point and was not infiltrated.

Superficial Inguinal Glands.—On the right side the one nearest the tumour was slightly enlarged and showed irregular caseous patches replacing about half the substance; other glands in this group appeared normal.

The glands on the left side were congested but otherwise normal.

Right Precrural Gland.—Normal.

Left Precrural contained a yellow caseous tubercle.

Iliac and Lumbar Glands were slightly congested; they showed no naked-eye evidence of tuberculosis.

Abdomen.

Omentum and Peritoneum.—Normal.

The Spleen was normal in size; it contained in the pulp from twenty to twenty-four greyish white nodules ranging in size from a pin's head to a pea; the larger nodules had opaque yellow centres.

The Liver, slightly adherent to diaphragm, showed in the substance sparsely scattered grey tubercles the largest the size of a millet seed; the latter were slightly opaque in the centre.

Kidneys and Suprarenal Bodies.—Normal.

Thorax.

Heart.—Normal.

Lungs.—The lungs were deeply congested; the greater part of the middle lobes, portions of the cephalic lobes, and several lobules along the sternal borders of the caudal lobe were dark red, firm, and quite airless; they showed a few small tubercles and on close inspection grey spots were seen. In the crepitant portions of the lung there were moderately numerous yellow tubercles, the size of pins' heads; in the thin margin of the left caudal lobe there were several nodules, the largest the size of a pea, yellow and gritty in the centre. On the surface of the caudal lobes there were several small projecting nodules and numerous long strands of connective tissue, some of which grew from the surface of the nodules; the fringes around the margins of the caudal lobes were hypertrophied, congested, and contained, chiefly on the left side, firm caseating nodules, the largest the size of a pea.

The Bronchial and Mediastinal Glands were deeply congested, but were not obviously tuberculous.

Pleura.—In several places along the margins of the ribs the lymphatic fringes were slightly hypertrophied and contained little grey granules; here and there a slightly larger nodule was seen similar to those on the diaphragm.

Diaphragm.—The pleural surface showed numerous hard grey tubercles, the majority the size of millet seeds; these were situated at the points of attachment of congested connective tissue processes; the fringes around the margins of the tendon were considerably hypertrophied, and showed here and there caseous nodules, the largest the size of a split pea; some of these nodules were hæmorrhagic and were attached to the free extremity of a connective tissue strand.

On the Peritoneal Surface of the diaphragm there were numerous hard grey nodules, the largest the size of a wheat grain.

Tongue, Tonsils, and Pharynx.—Normal.

Submaxillary, Pharyngeal, and Cervical Glands.—Normal.

Prescapular, Prepectoral, and Popliteal Glands.—Normal.

Large and Small Intestines.—Normal.

Mesenteric Glands.—A gland in the anterior part of the mesentery contained a cheesy, gritty nodule, the size of a pea; in the terminal mesenteric gland there was a similar but much smaller nodule.

Microscopical Examination.

Left Precrural Gland.—Three tubercle bacilli seen.

Mesenteric Gland.—No tubercle bacilli.

Bronchial Gland.—No tubercle bacilli.

PIG 96.

Subcutaneous Inoculation of culture from Pig 16.

Dose.—0·1 milligramme.

Date.—January 10, 1905.

Weight.—January 17, 1905. 1 qr. 23 lbs.

Killed.—September 7, 1905. 240 days after inoculation.

Clinical History.

The pig was inoculated subcutaneously in the wall of the abdomen on January 10, 1905.

Three weeks after inoculation a small nodule was felt under the skin of the abdomen and the superficial inguinal glands were slightly enlarged. The tumour and glands increased a little in size and then diminished.

The animal was in fair condition when killed, and, beyond the fact that it was somewhat stunted in its growth, had not shown any signs of illness during the experiment.

The temperature was slightly raised on the 23rd and 24th days (maximum 39·6° C.), and again on the 67th day to 39·2°C.; otherwise the temperature was normal throughout.

Weights.

In the first ten weeks there was a gain in weight of 26 lbs.; in the 12th week there was a loss of 10 lbs., and for three weeks subsequently the weight showed slight fluctuations; during the rest of the experiment there was a slight, almost steady increase in weight.

January 17th, 1905 -	- 1 qr. 23 lbs.
September 7th, 1905 -	- 3 qrs. 19 lbs.
Gain in weight - -	- 1 qr. 24 lbs.
Rate of gain per week -	- 1·56 lbs.

Post-mortem Examination.

Local Lesion.—In the subcutaneous tissues to the right of the umbilicus, there was a softened, caseous, slightly gritty nodule, the size of a kidney bean; the skin was not adherent.

Superficial Inguinal Glands.—On the right side there were two moderately enlarged glands, which were caseous and softened practically throughout; the capsules of the glands were thickened; gritty particles could be detected in the caseo-pus when rubbed between the finger and thumb; in this group were also a pea-sized caseous gland, and two normal glands. On the left side one gland contained a nodule about 1 cm. in diameter with fibrous wall and caseo-purulent contents; a second gland showed on section a number of discrete yellow caseous nodules (largest size of wheat grain) embedded in fibroid glandular tissue; other glands on this side were normal.

Precrural Glands.—Normal.

Iliac Glands.—Normal.

Abdomen.

Omentum and Peritoneum.—Normal.

The Spleen contained three millet seed sized tubercles, with soft yellow centres, in one case gritty, and translucent fibrous margins.

Liver.—Embedded in the substance of the liver just under the capsule a moderate number of nodules was seen (about four dozen counted on the anterior surface, and three dozen on the posterior); the nodules ranged in size from about 1·5 up to 7 and 8 mm. in diameter; all, with the exception of one or two of the smallest, which were grey and translucent throughout, had fibrous capsules and soft viscid caseous contents; in the latter fine gritty particles could be detected; on section similar nodules were seen in the depth of the liver.

Portal Glands.—In the small omentum there was a group of four enlarged glands, the capsules of which were adherent; on section the gland tissue was completely replaced by soft, cheesy, slightly gritty, caseous material; the capsules of the glands were much thickened.

Cœliac Glands were moderately enlarged and contained discrete yellow caseous nodules the size of wheat grains; two others contained similar nodules, but these in one or two places had run together to form soft caseous collections.

Lumbar Glands.—A gland on the left side of a lumbar vertebra showed about half its substance caseous and softened.

Kidneys and Suprarenal Bodies.—Normal.

Thorax.

Heart and Pleura.—Normal.

The Lungs contained sparsely scattered hard tubercles, the largest the size of a wheat grain; the tubercles were translucent and fibrous, and most had opaque yellow centres, which in several were quite calcareous; the tubercles were most numerous in the right cephalic and middle lobes, and many of these were translucent throughout; the lungs were crepitant and there were no areas of consolidation; in the fringes around the margins of the right caudal lobe were several tubercles.

The Bronchial Glands on each side were moderately enlarged; on section their capsules were thickened and their substance almost completely replaced by soft, cheesy, slightly gritty, caseous material.

The Dorsal Mediastinal Glands were normal.

Ventral Mediastinal Glands.—One, the size of a Barcelona nut, was caseous throughout; another similar in size showed discrete yellow caseous nodules, each about 2 mm. in diameter; the gland tissue between the nodules showed an increase in interstitial connective tissue.

A small gland just within the entrance to the thorax contained two yellow millet seed sized tubercles.

Diaphragm.—On the left side of the diaphragm projecting under the peritoneum were three or four hard translucent nodules, the largest the size of a small kidney bean; the latter had a soft, yellow centre.

On the Serous Surface of the stomach near the œsophagus there were about half-a dozen nodules, the largest the size of a wheat grain; one had a soft caseous centre the others were translucent throughout.

A gland near the angle of the jaw on the left side contained a pea-sized firm caseous nodule.

The right Pharyngeal Gland contained a small collection of viscid caseo-pus.

Other Glands in the Neck were normal.

Intestines.—Normal.

Mesenteric Glands.—Two glands in the anterior part of the mesentery contained each a pea-sized softened caseous nodule; a gland towards the root of the mesentery showed two pinhead-sized caseous foci.

Colic Glands.—Normal.

Prescapular and Prepectoral Glands.—Normal.

Testicles.—Normal.

Microscopical Examination (Smear Preparations).

Portal Gland (Emulsion for G.P.).—No tubercle bacilli.

Bronchial Gland (Emulsion for G.P.).—No tubercle bacilli.

Animals Inoculated,
With Tissue Emulsions.

Guinea-pig 1679, inoculated intraperitoneally with an emulsion of a portal gland, died of general tuberculosis in 38 days.

Guinea-pig 1680, inoculated intraperitoneally with an emulsion from a bronchial gland, died of general tuberculosis in 33 days.

With Culture.

Rabbits.

Number of Rabbit.	Initial Weight in grammes.	Final Weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
558	1,620	1,090	1·0 mg.	Subcutaneous	Died, 81 days	General tuberculosis.
559	1,510	1,140	0·1 mg.	Subcutaneous	Died, 137 days	General tuberculosis.
560	1,310	1,000	0·01 mg.	Subcutaneous	Died, 106 days	General tuberculosis.

CALF 230.

Subcutaneous Inoculation of culture from Pig 16.

Dose.—50 milligrammes.

Date.—January 10, 1905.

Weight.—January 17, 1905. 3 qrs. 3 lbs.

Died.—February 13, 1905. 34 days after inoculation.

Clinical History.

The calf was inoculated subcutaneously on the left side of the neck on January 10, 1905.

Two days later a small swelling was felt; this rapidly increased in size, and on January 30, 20 days after inoculation, attained its maximum, measuring 6 in. in length, 3 in. in breadth, and about ¾ in. in greatest thickness; on this date the left prescapular gland measured 3¼ in. in long diameter and a prepectoral gland was the size of a walnut. The skin over the upper part of the tumour then broke down, discharging serous fluid.

On February 6 the respirations were noticed to be increased and the animal looked ill and thinner.

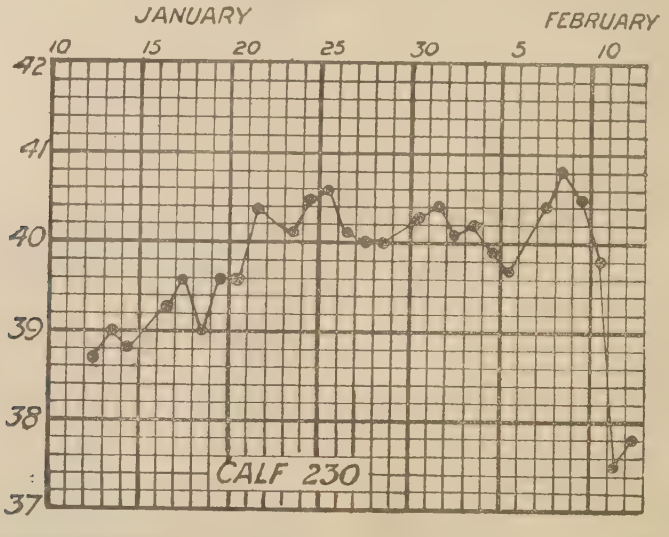
The symptoms rapidly increased in severity; the respirations became quicker, and finally laboured, and the animal visibly lost flesh. Death took place on February 13, 1905, 34 days after inoculation.

Weights.

There was a steady loss in weight.

January 17, 1905	- -	3 qrs. 3 lbs.
February 7, 1905	- -	3 qrs. 0 lb.
February 13, 1905	- -	2 qrs. 18 lbs.
Loss in Weight	- -	13 lbs.
Rate of Loss per Week	-	3·36 lbs.

Temperature



Post-Mortem Examination.

Carcass.—Emaciated.

Seat of Inoculation.—At the seat of inoculation, on the left side of the neck, there was a flat elongated tumour 6 in. by 2¾ in. by 1 in. On section it consisted of dense yellow caseo-necrotic tissue, adherent to the skin, and slightly infiltrating the muscles; in the upper part of the tumour there was an empty cavity 2 in. by 1½ in., whose walls were formed by breaking down caseated tissue; the skin over the cavity was infiltrated up to the surface, and in the central part ulcerated and necrosed.

The tissues around the tumour were slightly œdematous.

Left Prescapular Gland.—Weighed about 2 ozs., and measured 3 in. by 1½ in. by 1 in. On section it was composed throughout of dense pinkish yellow caseated tissue.

Left Prepectoral Glands.—The rounded prepectoral gland was three quarters of an inch in diameter, and on section resembled the prescapular. The kidney-shaped prepectoral and a small gland near it were œdematous, but were otherwise unaltered to the naked eye.

Cervical Glands.—A mid cervical gland on the left side showed the cortex partly caseous. All other cervical glands contained discrete caseous tubercles.

Abdomen.

Omentum.—Was quite devoid of fat. On the under surface there were a few pinhead-sized tubercles.

Spleen.—8 ozs. Normal on the surface; substance packed with firm yellow tubercles, ranging in size from 1·5 millimetres to about 3 millimetres in diameter.

Liver.—Weighed 3 lbs., and was not apparently enlarged. The substance was evenly peppered with grey tubercles, ranging in size from a mere point to that of a pin's head; the larger tubercles were slightly opaque in the centre.

Gall Bladder.—There were two or three yellow tubercles under the mucous membrane.

Portal Glands.—Were moderately enlarged. They showed in their cortices firm grey tissue, closely studded with irregular caseous foci.

Pancreas.—In the substance there was a minute yellow point.

Kidneys.—Right kidney showed in the cortex moderately numerous opaque grey miliary tubercles, some of which on section were seen to be slightly elongated in a radial direction. Left kidney similarly affected. No tubercles were seen in the medullary zones.

Suprarenal Bodies.—In the cortex of each suprarenal there was a greyish white focus.

Coeliac Glands.—Were enlarged, and resembled on section the portal.

Thorax.

Heart.—Muscle pale and flabby; cavities filled with ante-mortem blood clot; on the endocardium of the right ventricle there was a mustard seed-sized pearly tubercle.

Parietal Pleura and Diaphragm.—Normal.

Lungs.—Were moderately closely beset with opaque miliary tubercles; the right, middle and caudal lobes were solid, dark red in colour, and sank in water (animal found dead on right side); the right cephalic and the left lobes showed patches of consolidation, mainly small, which surrounded small groups of tubercles.

Mediastinal Glands.—The dorsal mediastinal glands showed a moderate degree of enlargement. On section they showed in the cortex firm grey tissue in a state of early caseation (they resembled the portal glands); the medullæ were congested.

Bronchial Glands, Peribronchial Glands.—Were enlarged, and on section resembled the mediastinal.

The gland below the trachea was enlarged, congested and œdematous; no foci of caseation seen.

The ventral mediastinal glands each showed one or two caseous tubercles.

Alimentary Tract.

Tonsils.—Contained a few caseous tubercles. On the superior surface of the soft palate there were two or three small ulcerated caseous nodules.

Small Intestine.—Under the mucous membrane of the small intestine there were sparsely scattered caseous tubercles; these were most numerous in the ileum.

Large Intestine.—Normal.

Gastric Glands.—Were enlarged, and composed practically throughout of grey translucent tissue, studded with minute opaque foci.

Mesenteric Glands.—The glands in the anterior three-fourths of the mesentery showed here and there opaque miliary tubercles; those in the posterior quarter were more severely affected.

Various Lymphatic Glands.

Colic Glands.—Several contained miliary tubercles.

Submaxillary Glands, Pharyngeal Glands were closely beset with caseous tubercles.

Gluteal Glands, Popliteal Glands, Pudic Glands, Precrural Glands, Iliac Glands, Sacro-Iliac Glands, Right Prescapular Gland, Right Axillary Gland.—Contained a moderate number of caseous tubercles.

Right Prepectoral Glands.—One right prepectoral gland showed a caseous focus.

Lumbar Glands.—Showed numerous caseous foci.

Ischiatic Glands.—Appeared normal.

Testicles, Eyes.—Normal.

Microscopical Examination.

Tonsils.—Tubercle bacilli moderateiy numerous.

Soft Palate, *Pancreas*, *Gall Bladder*—Tubercle bacilli numerous.

Heart.—One tubercle bacillus.

Right Suprarenal Body, *Left Suprarenal Body*—A few tubercle bacilli in each.

Tables showing the Virulence for

RABBITS

of Cultures derived from the different Animals in the Report on Modification Experiments.

Strains of Virus B. I.

Rabbits Inoculated with Culture derived from Monkey 76.

The culture used was the 5th generation, 20 days old, and had been in cultivation 91 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
189	3,560	1,920	0·1 mg.	Intravenous	24 days (died)	Lungs packed with grey miliary tubercles with yellow centres; numerous tubercles in the kidneys and numerous minute grey foci in the liver and spleen; latter organ much enlarged; all the lymphatic glands contained caseous foci.
192	2,930	1,870	1·0 mg.	Intravenous	16 days (died)	General tuberculosis as in Rabbit 189, but tubercles more minute.
190	3,050	1,970	1·0 mg.	Intraperitoneal	23 days (died)	Omentum retracted, slightly thickened and in a state of early caseation. Parietal and visceral peritoneum uniformly and closely covered with small opaque tubercles. Liver and spleen closely beset with minute tubercles; kidneys showed fairly numerous tubercles; lungs packed with miliary caseating tubercles; all the lymphatic glands were tuberculous, the sternal glands being caseous throughout
191	2 830	1,600	1·0 mg.	Intraperitoneal	32 days (died)	General tuberculosis as in Rabbit 190, but tubercles a little larger.
193	3,580	2,400	1·0 mg.	Subcutaneous	47 days (died)	Caseous tumour between scapulæ; skin over it ulcerated; neighbouring glands caseous; lungs crowded with caseating nodules; cephalic lobes solid; numerous tubercles in liver and kidneys; spleen greatly swollen, packed with caseous nodules, up to 5 mm. in diameter; most of the lymphatic glands were affected.
194	2,960	2,360	1·0 mg.	Subcutaneous	63 days (died)	General tuberculosis; the local lesion was situated between the scapulæ and was large, firm and caseous.

Rabbits Inoculated with Culture derived from Monkey 80.

The subculture used was the 6th generation, 20 days old, and had been in cultivation 177 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
216	920		0·1 mg.	Intravenous	8 days (died)	Cause of death not ascertained.
217	1,370	970	0·1 mg.	Intraperitoneal	37 days (died)	General tuberculosis; lungs packed with confluent caseating nodules.
218	1,220	920	1·0 mg.	Intraperitoneal	47 days (died)	General tuberculosis; tubercles were fairly numerous on the mesocolon, but sparsely scattered; on the parietal peritoneum; there was a bean-sized caseous nodule in the abdominal wall (the inoculation was partly subcutaneous).
219	1,100	980	1·0 mg.	Subcutaneous	42 days (died)	Caseous abscess between the scapulæ; general tuberculosis, lungs severely affected.
220	1,000	700	1·0 mg.	Subcutaneous.	49 days (died)	Firm caseous tumour breaking down in the centre, on left scapula; neighbouring glands caseous; lungs enlarged and composed almost entirely of caseating nodules; numerous tubercles in spleen and kidneys; liver packed with firm grey nodules; there were a few minute tubercles in the omentum and on the mesentery.

RABBITS INOCULATED WITH CULTURE DERIVED FROM MONKEY 82.

The subculture used was the 5th generation, 20 days old, and had been in cultivation 169 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose	Method of Inoculation.	Duration of Life.	Result.
221	1,050	850	0·1 mg.	Intravenous	26 days (died)	Lungs packed with miliary tubercles; numerous tubercles in kidneys and numerous very minute grey foci in liver and spleen.
222	1,320	950	0·1 mg.	Intraperitoneal	46 days (died)	Omentum thickened and caseating; sparsely scattered caseous tubercles on parietal peritoneum; very numerous tubercles on mesentery and meso-colon; a few minute tubercles in liver and spleen and a few miliary caseating tubercles in each kidney; lungs almost completely consolidated, being filled with confluent caseating nodules.
223	1,150	1,170	1·0 mg.	Intraperitoneal	91 days (died)	Omentum thickened and composed of lobulated masses of firm caseating tissue, the margins of which were darkly pigmented. Yellow caseous tubercles with pigmented margins were sparsely scattered over the surface of the parietal and visceral peritoneum. The spleen and liver showed a few flattened tubercles on the surfaces: none were seen in the depth. The kidneys were closely beset with caseating nodules. The lung tissue was extensively replaced by irregular caseating masses, in some cases softened. Sternal glands caseous throughout; the bronchial showed caseous foci. The diaphragm was thickened and caseating and there were some flattened growths on the parietal pleura.
224	1,200	870	10·0 mg.	Intraperitoneal	21 days (died)	General tuberculosis; tubercles very numerous on the peritoneum and in all the organs.
225	1,250	1,910	1·0 mg.	Subcutaneous	114 days (died)	Caseous ulcer between the shoulders; neighbouring glands large and caseous; moderate number of tubercles in omentum; lungs severely affected, consisting almost throughout of caseating tuberculous masses; a few miliary tubercles in each kidney; no tubercles in liver or spleen. The abdominal and thoracic lymphatic glands appeared normal.

Rabbits Inoculated with Culture derived from Baboon 64.

The subculture used was the 4th generation, 22 days old and had been in cultivation 99 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
857	1,760	1,200	0·1 mg.	Intravenous	21 days (died)	Lungs closely beset with grey miliary tubercles caseous in the centre; thoracic glands enlarged and oedematous, showed patches of caseations in the cortices; spleen greatly enlarged and swollen, pulp speckled with grey foci; liver closely beset with grey foci; numerous small grey tubercles in each kidney; most of the lymphatic glands contained caseous foci and there were minute grey points in the heart muscle.
858	1,630	1,070	0·1 mg.	Intraperitoneal	15 days (died)	Omentum thickened and caseating: parietal and visceral peritoneum covered with minute grey tubercles; lungs contained numerous grey tubercles with slightly opaque centres; spleen slightly enlarged; liver contained psorosperm nodules and minute grey points; a few minute tubercles just visible in the kidneys.
859	1,060	880	0·1 mg.	Intraperitoneal	16 days (died)	General tuberculosis resembling that in Rabbit 858; lungs were packed with grey tubercles, with opaque centres, which caused almost complete consolidation of all the lobes.
860	1,000	850	1·0 mg.	Subcutaneous	91 days) (killed, dying)	General tuberculosis.

Rabbits Inoculated with Culture derived from Pig 16.

The culture used was the 10th generation 20 days old, and had been in cultivation 359 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
159	1,700	1,200	1·0 mg.	Intravenous	21 days (died)	Lungs closely beset with miliary tubercles just beginning to caseate; bronchial glands showed caseous nodules; the liver and a greatly swollen spleen contained innumerable minute grey foci; there were moderately numerous early tubercles in each kidney.
158	1,000	1,070	1·0 mg.	Intraperitoneal	62 days (died)	General tuberculosis; there was a large caseous nodule in the muscle wall: inoculation probably partly intra-muscular.

Rabbits Inoculated with Culture derived from Pig 96.

The culture used was the 4th generation, 22 days old, and had been in cultivation 88 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in gam mes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
558	1,620	1,090	1·0 mg.	Subcutaneous	81 days (died)	Caseous ulcer ; widespread generalised tuberculosis ; lungs filled with caseating nodules.
559	1,510	1,140	0·1 mg.	Subcutaneous	137 days (died)	Caseous ulcer ; inguinal and axillary glands enlarged and caseous ; lungs enlarged and extensively tuberculous ; kidneys contained numerous nodules up to 12 mm. ; spleen normal ; there were two doubtful tubercles in the liver : many lymphatic glands were tuberculous ; the left lobe of the thyroid was almost entirely caseous, and there was a caseous nodule in that of the right.
560	1,310	1,000	0·01 mg.	Subcutaneous	106 days (died)	Caseous ulcer ; general tuberculosis ; the lungs were crepitant and contained only a moderate number of discrete nodules ; there was one tubercle in the spleen and a doubtful tubercle in the liver.
561	1,220	1,100	0·001 mg.	Subcutaneous	50 days (died)	Widespread generalised tuberculosis ; the omentum was thickened and caseating, and there were scattered tubercles on the peritoneum ; the inoculation was therefore partly intraperitoneal.

Rabbits Inoculated with Culture derived from the Spleen of Baboon 66.

The culture used was the 4th generation, 20 days old ; the total age of the culture was 149 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
984	1,580	1,180	1·0 mg.	Intravenous	Died, 14 days	Miliary tuberculosis of lungs ; numerous minute tubercles in spleen (very large), liver and kidneys.
985	1,410	1,090	0·1 mg.	Intravenous.	Died, 26 days	General tuberculosis ; tubercles very numerous in all the organs.
987	1,210	870	1·0 mg.	Intraperitoneal	Died, 12 days	General tuberculosis ; omentum thickened and caseating ; parietal and visceral peritoneum closely covered with minute tubercles ; numerous minute grey foci in liver and spleen ; a few in each kidney ; moderate number of minute tubercles in the lungs ; tuberculosis of abdominal and thoracic lymphatic glands.
986	1,030	—	0·1 mg.	Intraperitoneal	Died, 1 day	Severe coccidiosis of liver.

Strain of Virus B. II.

Rabbits Inoculated with Culture derived from Guinea-pig 1,735, the last of a Series of 24 Guinea-pigs, the first of which was Inoculated with the Original Material of Virus B. II.

The Culture used was the 9th generation, 12 days old ; the total age of the Culture was 300 days.

Number of Rabbit	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
1,027	1,870	1420	1·0 mg.	Intravenous	Died, 15 days	General tuberculosis.
1,024	1,020	950	0·1 mg.	Intravenous	Died, 18 days	General tuberculosis.
1,025	1,020	920	0·1 mg.	Intravenous	Died, 18 days	General tuberculosis.
1,026	1,150	820	1·0 mg.	Intraperitoneal	Died, 12 days	General tuberculosis ; tubercles everywhere numerous and very minute.
1,028	960	970	0·1 mg.	Intraperitoneal	Died, 29 days	General tuberculosis: numerous tubercles on peritoneum and mesentery ; liver and spleen packed with grey foci ; caseous tubercles in many of the lymphatic glands.

Strains of Virus B IV.

Rabbits Inoculated with Culture derived from Chimpanzee 4,

The culture inoculated was the third generation, 19 days old ; the total age of the culture was 46 days.

Number of Rabbit.	Initial Weight in Grammes.	Final Weight in Grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
166	2,150	1,460	0·1 mg.	Intravenous	28 days (died)	General tuberculosis ; lungs closely packed with miliary tubercles with caseous centres ; liver and spleen closely beset with minute tubercles; each kidney contained fairly numerous miliary tubercles ; many of the lymphatic glands showed minute caseous foci.
167	2,320	1,750	0·1 mg.	Intraperitoneal	39 days (died)	General tuberculosis; the peritoneum was covered with tubercles, and there were numerous tubercles in the lungs, spleen, and liver ; the kidneys contained only a few.
168	2,400	1,950	1·0 mg.	Intraperitoneal	61 days (died)	General tuberculosis ; there was a small caseous nodule in the subcutaneous tissues, and a larger one in the muscles of the abdominal wall.
169	2,660	1,890	1·0 mg.	Intraperitoneal	24 days (died)	General tuberculosis ; tubercles were very numerous on the peritoneum and in the lungs ; the spleen and liver were peppered with minute grey foci, and there were fairly numerous tubercles in each kidney: the sternal glands were caseous throughout ; the bronchial glands contained caseous tubercles.
170	2,250	1,550	1·0 mg.	Subcutaneous	74 days (died)	General tuberculosis ; lungs severely affected.
171	2,000	1,640	1·0 mg.	Subcutaneous	94 days (died)	Local caseous ulcer ; adjacent gland caseous ; lungs enlarged and composed practically throughout of caseating nodules ; there were very numerous nodules in the kidneys and none in the liver or spleen ; several lymphatic glands contained caseous tubercles.

RABBITS INOCULATED WITH CULTURE DERIVED FROM CHIMPANZEE .

The culture inoculated was the 3rd generation, 21 days old ; the total age of the culture was 49 days.

Number of Rabbit.	Initial Weight in Grammes.	Final Weight in Grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
240	1,360	1,040	0·1 mg.	Intravenous	18 days (died)	Lungs, œdematous and congested, packed with miliary tubercles ; spleen (enlarged) and liver speckled with minute grey foci, numerous miliary caseating tubercles in each kidney. There were a few tubercles on the endocardium of the right ventricle. The thoracic glands showed caseous areas in the cortices ; the iliac and lumber glands caseous foci ; numerous tubercle bacilli were found in the marrow.
242	840	720	0·1 mg.	Intraperitoneal	31 days (died)	General tuberculosis ; all the organs were affected, the lungs and kidneys severely.
239	1,620	1,140	1·0 mg.	Intraperitoneal	20 days (died)	General tuberculosis ; there were very numerous tubercles on the peritoneum (parietal and visceral) and in all the organs.
244	680	570	1·0 mg.	Intraperitoneal	19 days (died)	General tuberculosis ; similar to that in Rabbit 239.
241	1,260	1,070	1·0 mg.	Subcutaneous	77 days (died)	General tuberculosis ; the local lesion was a large baggy cyst, situated over the left scapula, containing blood-stained serous fluid and large caseo-necrotic masses ; the lungs were enlarged and extensively tuberculous.
243	730	910	1·0 mg.	Subcutaneous	62 days (died)	Local caseous ulcer ; inguinal and axillary glands much enlarged and extensively caseous ; tuberculosis of all the organs and most of the lymphatic glands ; the lungs were almost completely consolidated.

RABBITS INOCULATED WITH CULTURE DERIVED FROM CHIMPANZEE 8.

The culture inoculated was the 6th generation, 20 days old ; the total age of the culture was 84 days.

Number of Rabbit.	Initial Weight in Grammes.	Final Weight in Grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
320	1,210	1,000	0·1 mg.	Intravenous	16 days (died)	General tuberculosis.
321	1,190	1,100	1·0 mg.	Intraperitoneal	14 days (died)	General tuberculosis (uncomplicated); there were very numerous minute tubercles on the peritoneum and in all the organs. Tubercle bacilli were found in the bone marrow.
323	970	850	0·1 mg.	Intraperitoneal	5 days (died)	No sign of disease.
324	560	470	0·1 mg.	Subcutaneous	64 days (died)	Caseous ulcer ; adjacent glands caseous ; the lungs contained numerous caseating tubercles and irregular caseous patches ; there were sparsely scattered tubercles in the kidneys ; no tubercles were seen in the spleen or liver.
322	1,030	860	1·0 mg.	Subcutaneous	53 days (died)	General tuberculosis.
325	850	670	1·0 mg.	Subcutaneous	8 days (died)	Caseous patch in subcutaneous tissues of abdominal wall ; inguinal slightly enlarged and congested ; no sign of disease elsewhere. Microscopical. — Tubercle bacilli numerous in an inguinal gland ; none found in the spleen.

RABBITS INOCULATED WITH CULTURE DERIVED FROM CHIMPANZEE 10.

The culture inoculated was the 3rd generation, 21 days old ; the total age of the culture was 60 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
658	1,500	1,240	0·1 mg.	Intravenous	20 days (died)	Lungs packed with miliary tubercles ; liver and spleen peppered with minute grey points ; kidneys contained numerous submiliary tubercles ; there were numerous tubercles on the surface of the left ventricle and endocardium of the right.
660	1,780	1,370	1·0 mg.	Intraperitoneal	18 days (died)	General tuberculosis ; the tubercles were very numerous on the peritoneum and in all the organs.
662	1,520	1,290	0·1 mg.	Intraperitoneal	32 days (died)	General tuberculosis ; the lungs were closely beset with caseating miliary tubercles which caused almost complete consolidation of the anterior lobes ; the tubercles on the peritoneum and on the liver and spleen were not so numerous as in Rabbit 660.
664	1,570	1,240	0·01 mg.	Intraperitoneal	41 days (died)	General tuberculosis ; the lungs were extensively consolidated and composed practically throughout of greyish red translucent tissue containing irregular yellow caseous foci ; there were fairly numerous miliary tubercles in all the other organs and most of the lymphatic glands were tuberculous.
659	1,470	1,090	1·0 mg.	Subcutaneous	96 days (died)	Local ulcer ; tuberculosis of all the lymphatic glands and all the organs, except the spleen ; the lungs were severely affected and were almost quite solid. Each lobe of the thyroid contained an opaque tubercle.
661	1,430	1,430	0·1 mg.	Subcutaneous	85 days (died)	Large local ulcer ; nearest glands caseous ; lungs and kidneys closely beset with caseous nodules ; the liver appeared normal ; the spleen contained one tubercle ; most of the lymphatic glands were tuberculous ; the submaxilliary salivary gland contained a yellow tubercle and there was one tubercle in each lobe of the thyroid.
663	1,590	1,300	0·01 mg.	Subcutaneous	100 days (died)	General tuberculosis similar to that in Rabbit 659.

RABBITS INOCULATED WITH CULTURE DERIVED FROM CHIMPANZEE 16.

The culture inoculated was the 5th generation, 21 days old; the total age of the culture was 89 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
948	1,120	940	1·0 mg.	Intravenous	14 days (died)	General tuberculosis of the usual type for this mode of inoculation.
949	1,120	850	0·1 mg.	Intravenous	16 days (died)	
950	1,200		1·0 mg.	Intraperitoneal	9 days (died)	Slight tuberculosis of omentum and peritoneum and ventral mediastinal glands.
951	1,020	890	0·1 mg.	Intraperitoneal	42 days (died)	General tuberculosis; numerous tubercles in liver and spleen; the lungs were closely filled with grey tubercles, caseous in the centre; the cephalic lobes were quite airless.
954	1,570	1,220	·001 mg.	Intraperitoneal	54 days (killed)	Omentum thickened and considerably caseated; the spleen and liver contained moderately numerous submiliary tubercles; a few tubercles up to a hemp seed in each kidney; the lungs were large and filled with irregular translucent nodules with caseous foci.
955	1,200	820	·001 mg.	Intraperitoneal	45 days (died)	Omentum greatly thickened; scattered nodules up to a hemp seed on the visceral and parietal peritoneum; spleen showed moderately numerous yellow miliary tubercles, the liver a few; scattered grey tubercles with caseous centres in the kidneys; the lungs did not collapse and were fairly closely filled with irregular caseous areas. Mediastinal glands enlarged and caseous.
952	1,050	1,270	1·0 mg.	Subcutaneous	54 days (killed)	Softening caseous tumour the size of a pigeon's egg; three yellow miliary tubercles in the spleen; liver normal; kidneys showed nodules up to a small pea in size with little central caseation; the lungs were congested and contained numerous discrete tubercles with caseous centres; caseous foci in mediastinal, bronchial, and left iliac gland.
953	1,020	1,500	0·1 mg.	Subcutaneous	54 days (killed)	Shallow ulcer, 1¼in. in diameter, covered with a caseous scab; left axillary and inguinal glands partly caseous; spleen and kidneys each showed a single tubercle; liver normal; lungs are congested and show sparsely scattered translucent tubercles up to a millet seed.

Rabbits Inoculated with Culture derived from the Lung of Baboon 62.

The culture used was the 5th generation, 20 days old ; the total age of the culture was 91 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Methods of Inoculation.	Duration of Life.	Post-mortem Result.
874	2,100	1,630	0·1 mg.	Intravenous	Died, 19 days	General tuberculosis of the usual type.
873	1,850	1,360	0·1 mg.	Intraperitoneal	Died, 10 days	Omentum thickened ; fairly numerous tubercles on peritoneum ; a few minute grey tubercles in spleen and the kidneys ; moderately numerous tubercles in liver and lungs ; ventral mediastinal glands partly caseous.
872	1,500	1,950	1·0 mg.	Subcutaneous	Killed, 108 days	Small clean ulcer in skin, soft caseous nodules in nearest glands ; spleen, liver and left kidney normal, right kidney showed two grey tubercles with caseous centres ; lungs crepitant but slightly congested, contained scattered superficial nodules up to 4 mm. in diameter, soft and caseous in the centre, also a nodule 1 in. by 1½ in. filled with caseo-pus ; other lymphatic glands normal.

Rabbits inoculated with Culture derived from the Lung of Dog 92.

The culture used was the 4th generation, 22 days old ; the total age of the culture was 113 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
1009	1,400	990	1·0 mg.	Intravenous	Died, 14 days	General tuberculosis of the usual acute type.
1010	1,200	750	0·1 mg.	Intravenous	Died, 21 days	Ditto.
1013	1,250	620	1·0 mg.	Intraperitoneal	Died, 20 days	General tuberculosis ; the lungs were crepitant and contained only a moderate number of small tubercles
1011	1,200	850	0·1 mg.	Intraperitoneal	Died, 26 days	General tuberculosis ; tubercles were numerous in all the organs.
1012	1,200	1,540	1·0 mg.	Subcutaneous	Killed, 40 days	Soft caseous subcutaneous tumour size of pigeon's egg ; curdy caseous nodules in nearest glands ; one tubercle in the spleen and a few in each kidney ; a few scattered tubercles in the lungs.

RABBITS INOCULATED WITH CULTURE DERIVED FROM DOG 18.

The culture used for this series was the 9th generation, 20 days ; the total age of the culture was 249 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
410	1170	1730	0·1 mg.	Intravenous	97 days (killed)	The lungs were pinkish and collapsed normally; they showed evenly distributed throughout a moderate number of firm grey miliary tubercles with opaque centres. The left kidney showed in the depth of the cortex two grey miliary tubercles, slightly opaque in the centre. In the right kidney there was a similar tubercle and one of the calyces was filled with curdy caseo-pus. Other organs and all lymphatic glands were normal.
409	1530	1570	1·0 mg.	Intraperitoneal	97 days (killed)	The omentum contained scattered softened yellow nodules, up to 3 mm. in diameter and fairly numerous opaque pinhead sized tubercles; there were a few tubercles on the surface of the large intestine, liver and spleen, and a few groups of small tubercles on the mesentery between the vessels. The lungs contained a few grey miliary tubercles, slightly opaque in the centre, occurring chiefly in groups. The right kidney contained two or three minute grey tubercles in the cortex. The liver and spleen were normal on section. All lymphatic glands were normal.
411	1100	980	0·1 mg.	Intraperitoneal	68 days (died)	Omentum, not thickened, showed numerous spherical pearly white tubercles, smaller than pins' heads. There was a small number of similar tubercles on the mesentery, meso-colon and serous surfaces of the large intestine ; on the mesentery they formed clusters in the centres of the areas between the vessels. The lungs collapsed normally and contained a few grey tubercles, singly and in small groups, with very little central necrosis. Other organs and all the lymphatic glands were normal. The mucous membrane of the stomach was ulcerated.
408	1500	2170	1·0 mg.	Subcutaneous	97 days (killed)	In the subcutaneous tissues of the abdominal wall there was a thin-walled cyst, the size of a sparrow's egg, filled with thick creamy caseo-pus. Nearest glands normal. The right caudal lobe showed under the pleuræ a flattened congested nodule 5 mm. in diameter with a yellow caseous centre ; there was besides a pin-head sized grey tubercle opaque in the centre. There was no sign of tuberculosis elsewhere.
412	1020	1730	0·1 mg.	Subcutaneous	97 days (killed)	In the skin of the abdomen there was a small ulcer communicating with a small cavity with fibrous walls and caseo-purulent contents. In the right lobe of the lung there was a small irregular grey nodule containing minute caseous points. Other organs and all lymphatic glands were normal.
890	1520	1620	10·0 mg.	Intraperitoneal	83 days (killed)	Omentum contained translucent miliary tubercles with calcareous centres: a few similar tubercles on peritoneum: spleen and liver normal: three caseous miliary tubercles in the kidneys ; the lungs, pink and crepitant, showed a few translucent foci, two miliary tubercles and a grey marginal nodule with gritty foci ; lymphatic glands normal.

Strains of Virus B. IX.

Rabbits Inoculated with Culture derived from Chimpanzee 14.

The culture inoculated was the 4th generation, 22 days old ; the total age of the culture was 91 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
742	1,470	1,150	1·0 mg.	Subcutaneous	25 days (died)	In the subcutaneous tissues of the abdominal wall there was a caseous tumour the size of a pigeon's egg ; the neighbouring glands were enlarged and caseous ; there were two miliary tubercles in the lung. The pleural cavities contained a quantity of clear fluid, and the pericardial sac was distended with clear fluid containing a fibrinous clot. The left ventricle was hard, and on section showed the internal part of the wall, together with the musculi papillares, yellow and necrotic ; no tubercle bacilli were found.
743	1,270	980	0·1 mg.	Subcutaneous	103 days (died)	The local lesion was a thin-walled cavity, measuring $3 \times 2\frac{1}{4} \times 1\frac{1}{4}$, containing caseo-pus and firm caseous masses ; the nearest glands were enlarged and caseous ; the lungs did not collapse and were extensively tuberculous ; the kidneys contained sparsely scattered tubercles ; the liver and spleen were normal. The left lobe of the thyroid contained a small tubercle.
744	1,450	920	0·01 mg.	Subcutaneous	132 days (died)	The local lesion was a thin-walled cyst filled with caseo-pus ; one inguinal gland was caseous, the other neighbouring glands were normal ; the lungs contained numerous discrete caseous nodules, but were not so severely affected as usual ; the kidneys contained moderately numerous tubercles, the liver two, and the spleen none. Most of the lymphatic glands were normal. Each lobe of the thyroid contained a caseous focus.
745	1,350	920	0·001 mg.	Subcutaneous	151 days (died)	Shallow ulcer in the skin the size of a shilling ; inguinal glands enlarged and caseous throughout ; liver and spleen normal ; the kidneys contained moderately numerous tubercles ; the lungs were large and almost replaced by irregular caseous masses ; caseous masses on the diaphragm ; a nodule in each lobe of the thyroid.

Rabbits Inoculated with Culture derived from Chimpanzee 18.

The culture inoculated was the 2nd generation, 19 days old ; the total age of the culture was 36 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
993	1,540	1,150	1·0 mg.	Intravenous	16 days (died)	General tuberculosis of the usual type.
994	920	760	0·1 mg.	Intravenous	15 days (died)	
996	1,250	800	1·0 mg.	Intraperitoneal	17 days (died)	General tuberculosis.
995	900	540	0·1 mg.	Intraperitoneal	30 days (died)	General tuberculosis.
997	1,050	1,250	1·0 mg.	Subcutaneous	44 days (killed)	Local tumour the size of a hen's egg, caseo-purulent in the centre ; kidneys and spleen showed a few minute tubercles ; liver normal ; the lungs were pink and crepitant, containing a moderate number of grey tubercles with caseous centres up to the size of a millet seed.
998	840	1,150	0·1 mg.	Subcutaneous	44 days (killed)	The local lesion was a small ulcer with a caseous floor ; nearest glands caseous ; spleen contained a moderate number of yellowish tubercles the size of rape seed ; a few tubercles in each kidney ; the lungs were pink and crepitant with scattered translucent tubercles up to a millet seed.

Rabbits Inoculated with Culture derived from Monkey 110.

The Culture used was the 4th generation, 7 days; all the generations had been grown on glycerin media; the total age of the Culture was 55 days.

Number of Rabbit	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
521	1,380	1,010	1·0 mg.	Intraperitoneal	22 days (died)	General tuberculosis; very numerous minute tubercles on the parietal and visceral peritoneum; lungs beset with small tubercles; the spleen was swollen and showed barely visible grey points; foci not definitely visible in the liver; many lymphatic glands showed caseous foci.
522	1,680	1,550	0·01 mg.	Intraperitoneal	37 days (died)	General tuberculosis; the omentum was thickened and caseating; tubercles were moderately numerous on the parietal peritoneum, more numerous on the mesentery and meso-colon; there were tubercles in all the organs, the lungs being most severely affected; almost all the lymphatic glands were tuberculous.

Rabbits Inoculated with Culture derived from Monkey 116.

The Culture used was the 2nd generation, 18 days old; the total age of the Culture was 27 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
691	1,220	1,030	1·0 mg.	Subcutaneous	100 days (died)	Large ulcerated caseous lesion; adjacent glands caseous; the lungs were enlarged, extensively consolidated, and advanced in caseation; the kidneys contained moderately numerous nodules; liver and spleen normal.
692	950	770	0·01 mg.	Subcutaneous	20 days (died)	Softened caseous local lesion; inguinal glands, slightly enlarged, showed caseous foci in the cortices.
693	850	620	0·001 mg.	Subcutaneous	100 days (died)	The tuberculosis in this animal resembled that in Rabbit 691.

Rabbits Inoculated with Culture derived from Lemur 2.

The Culture used was the 6th generation, 23 days old; the total age of the Culture was 96 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
535	1,580	1,300	1·0 mg.	Intravenous.	14 days (died)	The lungs were crepitant and contained numerous, just visible small grey tubercles with caseous, centres. The spleen was much enlarged; (?) grey points in the pulp. Liver apparently infiltrated with extremely numerous minute grey points. No tubercles seen in the kidneys.
536	1,290	1,090	0·1 mg.	Intravenous	21 days (died)	Lungs crepitant, contained scattered miliary caseous tubercles; spleen (greatly enlarged) and liver beset with extremely numerous minute grey points; there were a few tubercles in the kidneys; bronchial glands showed early caseous foci.
537	1,850	1,290	1·0 mg.	Intraperitoneal	18 days (died)	General tuberculosis of the usual type.

Rabbits Inoculated with Culture derived from Baboon 68.

The culture used was the 3rd generation, 23 days old; the total age of the culture was 57 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
688	1,260	780	1·0 mg.	Subcutaneous	77 days (died)	Local ulcer; adjacent glands contained caseous nodules; lungs enlarged, extensively consolidated and caseated; there were moderately numerous nodules in the kidneys; the spleen and liver were normal; there were some caseous nodules in the walls of the intestines. The thoracic and abdominal (except one lumbar and one iliac) glands were normal.
689	1,560	820	0·01 mg.	Subcutaneous	129 days (died)	Small dry ulcer; neighbouring glands caseous; the lungs were crepitant and contained discrete caseous tubercles and nodules; thoracic glands, liver and spleen normal; moderately numerous caseous nodules in the kidneys; numerous flattened caseating growths on the diaphragm and pleura and large firm nodular caseating masses in the dorsal and ventral mediastina.
690	1,470	1,280	0·0001 mg.	Subcutaneous	187 days (killed)	Small shallow ulcer; nearest glands enlarged and caseous; spleen and liver normal; in the kidneys there were scattered caseous nodules up to one inch in diameter; the lungs were closely beset with grey tubercles up to a hemp seed; firm yellow caseous tumours in dorsal mediastinum, on pleura, pericardium, and pleural surface of the diaphragm.

Rabbits Inoculated with Culture derived from Monkey 126.

The culture was the 4th generation, 22 days; the total age of the culture was 64 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
1016	1,000	730	1·0 mg.	Intravenous	15 days (died)	General tuberculosis; lungs filled with small tubercles.
1015	1,300	1,050	0·1 mg.	Intravenous	19 days (died)	General tuberculosis.
1018	1,340	960	0·1 mg.	Intravenous	25 days (died)	General tuberculosis.
1014	850	—	1·0 mg.	Intraperitoneal	5 days (died)	Slight tuberculosis of omentum; no disease elsewhere.
1017	1,070	780	0·1 mg.	Intraperitoneal	28 days (died)	General tuberculosis of the usual type.

Rabbits Inoculated with Culture derived from Monkey 132.

The culture was the 4th generation, 22 days old; the total age of the culture was 50 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
1022	1,080	—	1·0 mg.	Intravenous	5 days (died)	No naked-eye evidence of tuberculosis.
1019	1,240	1,000	0·1 mg.	Intravenous	16 days (died)	General tuberculosis.
1020	1,440	1,150	0·1 mg.	Intravenous	21 days (died)	General tuberculosis.
1021	870	680	1·0 mg.	Intraperitoneal	23 days (died)	General tuberculosis.
1023	1,100	—	0·1 mg.	Intraperitoneal	5 days (died)	No visible disease.

RABBITS INOCULATED WITH CULTURE DERIVED FROM DOG 60.

The culture used was the 3rd generation, 21 days old, and had been in cultivation 64 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
637	2,610	1,860	0·1 mg.	Intravenous	Died, 28 days	General tuberculosis; lungs closely beset with miliary caseating coalescing tubercles.
638	2,280	1,730	0·1 mg.	Intraperitoneal	Died, 25 days	General tuberculosis; peritoneum profusely covered with small tubercles; lungs closely beset with discrete grey tubercles with caseous centres; numerous small tubercles in liver and kidneys; none visible in the spleen.
639	2,900	1,580	1·0 mg.	Intraperitoneal	Died, 28 days	General tuberculosis of the usual type.
641	1,180	900	0·1 mg.	Subcutaneous	Died, 78 days	General tuberculosis; lungs closely filled with caseating nodules; numerous tubercles in the kidneys, one minute tubercle in the spleen, none in the liver; most of the lymphatic glands were affected.
640	2,830	1,590	1·0 mg.	Subcutaneous	Died, 161 days	Softened caseous nodule the size of a hen's egg; nearest glands caseous; lungs extensively tuberculous; the kidneys contained numerous nodules; the liver a few doubtful tubercles; the spleen was normal; there were numerous tuberculous growths in the parietal pleura and the thyroid body; intestines and gall bladder were tuberculous.

RABBITS INOCULATED WITH CULTURE DERIVED FROM THE LIVER OF DOG 84.

The culture used was the 6th generation, 21 days old; the total age of the culture was 123 days.

Number of Rabbit.	Initial Weight in Grammes.	Final Weight in Grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
1003	1,320	950	1·0 mg.	Intravenous	Died, 17 days	Lungs packed with miliary tubercles; numerous minute foci in spleen (enlarged); liver, and kidneys.
1000	1,050	650	0·1 mg.	Intravenous	Died, 23 days	General tuberculosis; lungs packed with miliary tubercles.
1001	1,150	720	1·0 mg.	Intraperitoneal	Died, 21 days	General tuberculosis of the usual type.
1002	950	680	0·1 mg.	Intraperitoneal	Died, 32 days	General tuberculosis of the usual type.
999	850	1,250	1·0 mg.	Subcutaneous	Killed, 111 days	The local lesion consisted of a large thin-walled cyst containing a little purulent matter, contents having been evacuated through small ulcer in the skin; the nearest glands were partly caseous; the iliac glands consisted of bags of dark yellow caseo-pus; the liver and spleen were normal; the kidneys showed a few grey tubercles; the lungs collapsed, but were congested and contained a few miliary tubercles; in the margins also there were fibro-caseous nodules, one of which was filled with muco-pus. Both ankle joints and several metatarsal joints were distended with mucoid caseous substance containing numerous tubercle bacilli.

RABBITS INOCULATED WITH CULTURE DERIVED FROM THE LUNG OF DOG 50, THROUGH GUINEA-PIG 1708.

The culture used was the 3rd generation, 20 days old and had been in cultivation a total period of 75 days.

Number of Rabbit.	Initial Weight in Grammes.	Final Weight in Grammes.	Dose.	Method of Inoculation.	Duration of Life.	Result.
634	2,460	2,360	0·1 mg.	Intravenous	K. 91 days	The lungs were crepitant and contained a moderate number of flattened grey tubercles with caseous centres situated chiefly on the surface and around the margins of the lobes. Each kidney contained a few grey tubercles in the cortex, slightly opaque in the centre; in the medullary zone of one there was a fine caseous streak. There was one minute tubercle in the heart muscle and sparsely scattered yellow tubercles in the muscle of the back (T.B. were found in the latter).
633	2,730	2,360	1·0 mg.	Intravenous	K. 91 days	The lungs and kidneys in this case were more severely affected than in Rabbit 634. The ventral portions of the cephalic lobes were composed of translucent grey tissue with an irregular caseous network, the rest of the lobes being beset with grey caseating nodules here and there confluent. In the caudal lobes there were similar nodules, which around the margins and on the dorsal surfaces had become confluent. The bronchial glands contained one or two minute yellow tubercles. The kidneys each showed on the surface a moderate number of caseous nodules, largest 2 mm., most of which extended as radial streaks into the medulla, some nearly to the apex of the papilla; in the pelvis of one there was a small collection of caseo-pus. There were two pearly white tubercles in the liver: spleen normal.
636	1,530	930	0·1 mg.	Intraperitoneal	D. 68 days	Omentum slightly thickened and caseating; the parietal and visceral peritoneum showed moderately numerous translucent tubercles with caseous centres. The lungs contained sparsely scattered caseating nodules, up to 3·5 mm. mainly on the surface. Other organs and glands showed no tubercles.
632	1,800	1,300	1·0 mg.	Intraperitoneal	D. 81 days	Slight tuberculosis of peritoneum. The kidneys each showed a few caseous tubercles in the cortex and caseous streaks in the pelvis. The lungs contained fairly numerous irregular caseous areas and nodules with grey margins confined mainly to the outer part and margins of the lungs. There were minute opaque foci scattered about in the muscles (T.B. numerous).
635	1,650	1,950	1·0 mg.	Subcutaneous	K. 91 days	Small flat fibrous local lesion with a small amount of caseation. Two minute foci in one inguinal gland. About 10 small caseous nodules, with grey margins, in the lungs. No tubercles elsewhere.

Strain of Virus B XXII.

RABBITS INOCULATED WITH CULTURE DERIVED FROM THE LUNG OF DOG 72.

The culture was the 2nd generation, 22 days old ; the total age of the culture was 91 days.

Number of Rabbit.	Initial Weight in Grammes.	Final Weight in Grammes.	Dose.	Method of Inoculation.	Duration of Life.	Post-mortem Results.
867	1,500	910	0·1 mg.	Intravenous	26 days (died)	General tuberculosis of the usual type.
868	1,770	1,000	1·0 mg.	Intraperitoneal	19 days (died)	General tuberculosis ; parietal visceral peritoneum closely covered with minute tubercles ; minute foci just visible in spleen (enlarged) and liver.
869	1,690	--	0·1 mg.	Intraperitoneal	8 days (died)	Coccidiosis of liver.
870	1,760	1,160	0·1 mg.	Subcutaneous	55 days (died)	Local lesion size of a hen's egg ; neighbouring glands caseous ; the lungs were crepitant and contained a moderate number of nodules up to 3 mm. ; there were a few miliary tubercles in each kidney ; the spleen and liver were normal.
871	1,660	1.000	1·0 mg.	Subcutaneous	109 days (died)	The local lesion was a shallow ulcer, 1½ in. by ½ in. ; nearest glands partly caseous ; spleen and liver normal ; kidneys showed sparsely scattered tubercles up to a millet-seed ; the lungs were large and extensively caseated.

INFLUENCE OF GLYCERIN ON VIRULENCE.

All the cultures used in the estimation of the virulence of different viruses for rabbits have been isolated and maintained throughout on media free from glycerin. It has been shown that when cultures of the tubercle bacillus are subcultivated on glycerin media for several generations all viruses grow with increased luxuriance, and a series of experiments on rabbits was carried out to ascertain how far this increased saprophytic power had affected the virulence.

Several viruses have been subcultivated for varying periods on glycerin media. Five of these have been tested on rabbits and the virulence of four compared with that of cultures kept on serum alone.

With each of the latter cultures, four rabbits were inoculated subcutaneously with doses of 1·0, 0·1, 0·01, 0·001 mg. respectively. Four of the rabbits died in 15, 17, 22, and 34 days respectively, and one was killed after 34 days; one of the former died of tuberculosis, the inoculation having been partly intraperitoneal; in the others the tuberculosis was limited.

Another rabbit (No. 545) lived for 315 days, gaining 770 grammes in weight, and was killed in apparent good health. The post-mortem examination showed a limited amount of general tuberculosis, of an unusually chronic type.

All the other rabbits died of general tuberculosis, the disease, as usual after subcutaneous inoculation, being most severe in the lungs and kidneys.

The results of these have been analysed and are exhibited in tabular form.

Dose.	Serum Cultures.		Glycerin Serum Cultures.	
	Number of Rabbits.	Average Duration of Life.	Number of Rabbit	Average Duration of Life.
1·0 mg.	3	96 days	4	75·75 days
0·1 mg.	4	76·5 days.	3	103·6 days.
0·01 mg.	4	114·5 days.	3	81 days.
0·001 mg.	2	80·5 days.	3	108 days.

The duration of the experiments in each series of inoculations varied very considerably, and in several instances the rabbits inoculated with the smaller doses have died before those inoculated with the larger doses, for example, in one experiment the rabbit inoculated with 0·001 mg. succumbed before any of the other three inoculated with 1·0, 0·1, and 0·01 mg.

It is clearly impossible, therefore, to draw any conclusion from a comparison of the duration of life of animals inoculated with the same dose from the different cultures.

All that the experiments can be said to show is that the glycerin cultures gave rise to a tuberculosis identical in all its features with that set up by serum cultures.

The fifth culture was inoculated intravenously into four rabbits, the same doses being employed as for the rabbits inoculated subcutaneously. In this experiment no rabbits were inoculated with the culture grown on serum alone, but a comparison of these results with those obtained with an earlier generation of the serum culture demonstrates that the culture grown on glycerin serum had not undergone any diminution in virulence.

TABLES SHOWING THE COMPARATIVE VIRULENCE OF CULTURES GROWN SINCE ISOLATION ON SERUM ALONE AND OF THE SAME CULTURE GROWN FOR A PERIOD ON GLYCERIN MEDIA.

VIRUS B. XI. (RABBIT 66).

Rabbits inoculated with culture grown since isolation on pure serum.

The subculture used was the 16th generation, 20 days old.

The total age of the cultures in each case was 454 days.

Number of Rabbit.	Initial Weight in Grammes.	Final Weight in Grammes.	Dose.	Duration of Life.	Result.
573	2,560	1,550	1·0 mg.	82 days (died)	Very large caseous local lesion, the skin over which was freely moveable; it infiltrated the muscles, but did not involve the peritoneum: adjacent glands enlarged and caseous; lungs enlarged and packed with caseating nodules, confluent in the cephalic lobes; the spleen and liver contained each three small tubercles; the kidneys contained numerous caseating nodules 1 to 3 mm. in diameter; the portal and thoracic glands contained small discrete tubercles; the pleura showed a few flattened caseous nodules, and there were some caseous nodules in the appendix and dilated end of ileum.
564	1,150	1,000	0·1 mg.	71 days (died)	Local caseous ulcer; adjoining glands caseous; liver and spleen normal; kidneys and lungs very closely beset with caseating nodules; in the latter very little functional tissue remained; bronchial and lumbar glands slightly affected; there was one nodule on the pleura.
566	1,070	1,000	0·01 mg.	92 days (died)	Local ulcer; inguinal and iliac glands caseous; the lungs filled the chest and were extensively caseated; the spleen was normal; the liver contained one nodule (T.B.); the kidneys numerous nodules, up to 4 mm.; caseous foci in lumbar and bronchial glands; left lobe of thyroid enlarged and caseous throughout; caseous nodules in centre of a rib and numerous flattened nodules on the pleura.
568	1,260	1,110	0·001 mg.	64 days (died)	Large caseous local lesion infiltrating muscles of abdominal wall and involving peritoneum; skin not adherent; omentum contained a number of discrete caseous tubercles; the lungs were filled with irregular caseous nodules and masses; the kidneys contained a moderate number of caseous nodules; there was one tubercle in the spleen, and most of the abdominal and thoracic

Rabbits inoculated with culture grown for 199 days on pure serum and 255 days on glycerin media.

The subculture used was the 20th generation, 20 days old.

All the inoculations were made subcutaneously.

Number of Rabbit.	Initial Weight in Grammes.	Final Weight in Grammes.	Dose.	Duration of Life.	Result.
574	1,270	980	1·0 mg.	63 days (died)	Local caseous ulcer, 1 in. in diameter; neighbouring glands enlarged and caseous; the lungs filled the chest and were composed practically throughout of caseous nodules and masses; the spleen contained numerous caseous miliary tubercles; liver normal; the kidneys showed very numerous projecting caseous nodules with grey margins, up to 3 and 4 mm. in diameter; the bronchial, portal and mesenteric glands contained caseous tubercles; the appendix and dilated extremity of ileum contained numerous caseous tubercles.
575	1,210	870	0·1 mg.	22 days (died)	Flattened subcutaneous caseous patch, skin adherent, but not ulcerated; inguinal glands contained caseous nodules; sternal glands a little enlarged; no tuberculosis elsewhere; liver enlarged and packed with yellow nodules (psorospermosis).
576	1,330	1,420	0·01 mg.	81 days (died)	Caseous ulcer in abdominal wall; adjoining glands caseous; lungs enlarged and filled with caseous nodules; there were three tubercles in the spleen, two in the heart muscles, and four in the thyroid body, and numerous nodules (up to 1 cm.) in the kidneys; most of the lymphatic glands were affected.
577	1,070	1,150	0·001 mg.	102 days (died)	Large caseous tumour, not ulcerated; lungs and kidneys closely beset with caseating tubercles and nodules; spleen and liver normal; minute caseous tubercles in right lobe of thyroid; many lymphatic glands were tuberculous.

VIRUS B. IV. (Calf 138).

Rabbits inoculated with culture grown since isolation on pure serum.

The subculture used was the 15th generation, 21 days old.

The total age of the cultures in each case was 558 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Duration of Life.	Result.
542	1,090	870	1·0 mg.	115 days (died)	Ulcerated caseous lesion; neighbouring glands enlarged and caseous; lungs enlarged and extensively caseated; there was one tubercle in the spleen; none in the liver; the kidneys contained sparsely scattered nodules, the largest the size of a pea; there were moderately numerous miliary tubercles in the omentum; the right lobe of the thyroid was partly caseous; bronchial glands tuberculous.
543	1,400	900	0·1 mg.	94 days (died)	Large caseous lesion; skin ulcerated; nearest glands caseous; lungs firm and infiltrated with a caseous network; numerous nodules in the kidneys; spleen and liver normal; one tubercle in the thyroid body; caseous foci in mesenteric and ventral mediastinal glands; bronchial glands normal; the omentum contained a few minute tubercles.
544	1,390	1,000	0·01 mg.	103 days (died)	Local ulcer; adjoining glands caseous; lungs filled the chest and were closely beset with coalescing caseating nodules; there were three tubercles in the spleen, four in the liver and numerous projecting nodules in the kidneys; there were two tubercles in the heart muscle and a few in the omentum; most of the lymphatic glands in the body were caseating.
545	1,280	2,050	0·001 mg.	315 days (killed)	The local lesion was an elongated fibrous tumour containing caseo-purulent nodules; yellow calcareous granules in left inguinal gland; left iliac glands formed a mass of cysts filled with caseo-pus; kidneys and liver showed a few tubercles the size of rape-seed, spleen normal; lungs a little congested and œdematous, contained scattered miliary tubercles, some caseous in the centre, and several pea-sized nodules containing caseo-pus; a lumbar and a sternal gland were enlarged and filled with caseo-pus.

Rabbits inoculated with culture grown for 302 days on pure serum and 256 days on glycerine media.

The subculture used was the 19th generation, 21 days old.

All the inoculations were made subcutaneously.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Duration of Life.	Result.
538	1,120	800	1·0 mg.	94 days (died)	Shallow ulcer with caseous margins; inguinal glands partly caseous; lungs crepitant, collapsed normally; they contained scattered caseous nodules and small grey tubercles with opaque centres; liver and spleen normal; the kidneys together contained ten tubercles, largest three mm. in diameter; thoracic and most of abdominal lymphatic glands were normal; there were some miliary tubercles in the omentum.
539	1,410	1,000	0·1 mg.	135 days (died)	Elongated shallow ulcer covered with dry scab; inguinal glands caseous and softened; no tubercles in spleen; a few doubtful grey points in liver; lungs enlarged, tissue extensively replaced by large caseous masses; caseous tubercle in each lobe of thyroid; caseous points in iliac, lumbar and mesenteric glands; other glands normal.
540	1,240	830	0·01 mg.	129 days. (died)	Local ulcer; nearest gland caseous; lungs collapsed moderately well and contained fairly numerous caseous nodules up to 2 or 3 mm. (in this case there was more normal lung tissue than usual); kidneys contained numerous nodules varying much in size; spleen normal; liver, a few doubtful grey points; minute tubercle in right lobe of thyroid.
541	1,200	950	0·001 mg.	114 days (died)	Local ulcer covered with dry scab; nearest glands caseous; other lymphatic glands caseous to a varying extent; lungs closely beset with more or less discrete caseous nodules (moderate amount of crepitant lung tissue); one tubercle in spleen; none in liver; numerous nodules in kidneys; numerous miliary tubercles in omentum; numerous caseous nodules in vermiform appendix and dilated end of ileum; two tubercles in a submaxillary salivary gland; large caseous nodule in one rib, expanding the bone.

VIRUS B. IV. (Calf 118).

Rabbits inoculated with culture grown on serum alone.

The subculture used was the 24th generation, 21 days old.

Rabbits inoculated with culture grown for 490 days on pure serum, and for 263 days on glycerin media.

The subculture used was the 25th generation, 21 days old, and was grown on ox serum.

The total age of the cultures in each case was 753 days. All the inoculations were made subcutaneously.

Number of Rabbit.	Initial weight in grammes	Final weight in grammes.	Dose.	Duration of Life.	Result.	Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Duration of Life.	Result.
550	1,470	1,000	1·0 mg.	91 days (died)	Local ulcer; inguinal glands partly caseous; lungs enlarged and extensively caseated; kidneys contained numerous nodules, up to a pea in size; the spleen, two yellow tubercles; liver normal; numerous miliary tubercles in omentum, and a few flattened growths on the pleura; slight tuberculosis of thoracic and mesenteric glands.	546	1,450	960	1·0 mg.	58 days (died)	Large dense caseous tumour with a small ulcer in the skin; nearest glands caseous throughout; lungs closely beset with coalescing caseating nodules; kidneys contained numerous nodules; numerous tubercles in spleen and liver; bronchial, portal and coeliac glands partly caseous.
551	1 490	920	0·1 mg.	74 days (died)	Local ulcer; inguinal glands very large and caseous throughout; lungs contained moderately numerous caseous nodules; each kidney contained about a dozen; there were four caseous tubercles in the spleen, none in the liver; caseous tubercles in bronchial and mesenteric glands.	547	1,520	1,270	0·1 mg.	86 days (died)	Circular ulcer 1¼ inches in diameter; inguinal glands caseous throughout; lungs crepitant, contained moderately numerous discrete caseating tubercles; scattered miliary tubercles in kidneys; spleen and liver appeared normal; many lymphatic glands were caseous; three minute tubercles in the thyroid body.
552	1,840	1,150	0·01 mg.	90 days (died)	Local ulcer; inguinal glands large, caseous and softened; lungs extensively caseated; numerous caseous nodules, varying from a pin's head to a pea, in the kidneys; liver and spleen normal. Small caseous nodules in bronchial and mesenteric glands; two opaque foci in right lobe of thyroid.	548	1,830	1,230	0·01 mg.	128 days (died)	Large partially softened caseous tumour with a dry ulcer in the skin; nearest glands caseous; lungs closely beset with caseating nodules, confluent in places; the thoracic and most of the abdominal lymphatic glands were normal; spleen and liver normal; moderately numerous nodules in kidneys; left lobe of thyroid one third caseous.
553	1,440	1,450	0·001 mg.	34 days (killed)	Caseating local lesion; inguinal glands partly caseous; right caudal lobe contained one hard caseous tubercle, twice the size of a millet-seed; one tubercle in the spleen; no tubercles elsewhere.	549	1,440	1,130	0·001 mg.	34 days (died)	Flat ulcerated caseous lesion; inguinal glands partly caseous; there was a caseous focus in each iliac gland; the lungs contained two tubercles, one the size of a wheat grain, the other just visible; no tuberculosis elsewhere.

VIRUS B. XVIII. (DIRECT).

Rabbits inoculated with culture grown throughout on pure serum.

The subculture used was the 16th generation, 20 days old.

The total age of the cultures in each case was 316 days.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Duration of Life.	Result.
591	1,400	1,090	1·0 mg.	17 days (died)	Subcutaneous caseous lesion; omentum thickened and caseating; numerous minute tubercles on parietal and visceral peritoneum; sparsely scattered minute tubercles in lungs and minute grey foci in spleen and liver (inoculation partly intraperitoneal).
589	1,270	1,100	0·1 mg.	67 days (died)	Large irregular ulcer and general tuberculosis of the usual type; both the spleen and liver contained caseous tubercles.
590	1,140	1,250	0·01 mg.	173 days (died)	Very large cyst, with caseo-purulent contents in subcutaneous tissues of abdominal wall; neighbouring glands enlarged and caseous; lungs closely beset with coalescing caseating masses; kidneys packed with caseous nodules; liver and spleen appeared normal; omentum retracted and beset with caseating tubercles; tendon of diaphragm covered with firm fibro-caseous masses, 1 cm. in greatest thickness; large caseating masses in dorsal and ventral mediastina, latter completely covering costal cartilages; numerous filmy growths on parietal pleura; most of the lymphatic glands were caseous.
592	1,100	1,150	0·001 mg.	97 days (died)	Large caseous ulcerated lesion and general tuberculosis of the usual type, the lungs being the most severely affected; the liver contained psorosperm nodules, but no tubercles.

Rabbits inoculated with culture grown for 107 days on pure serum and for 209 days on glycerin serum.

The subculture used was the 16th generation, 20 days old, and was grown on ox serum.

All the inoculations were made subcutaneously.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Duration of Life.	Result.
595	1,490	1,150	1·0 mg.	88 days (died)	Large caseous softened lesion, ulcerated on the surface; neighbouring glands tuberculous; lungs crepitant, contained numerous discrete caseating tubercles, the largest the size of a hemp-seed; moderately numerous tubercles in the kidneys; a few grey points in the liver (T.B.) and one yellow tubercle in the spleen; thoracic glands partly caseous.
593	1,270	970	0·1 mg.	90 days (died)	Softened caseous tumour, with a small ulcer in the skin; neighbouring glands caseous; lungs contained a moderate number of discrete caseous nodules; the lung tissue intervening was normal in appearance; moderate number of caseous nodules in kidneys; one yellow tubercle in spleen; liver normal.
594	1,170	1,140	0·01 mg.	86 days (died)	Large softened caseous tumour, ulcerated on the surface; inguinal glands enlarged and caseous; lungs packed with caseating nodules; sparsely scattered nodules, mostly small, in kidneys; spleen enlarged, Malphigian bodies prominent; liver normal; opaque tubercle in thyroid body (T.B.).
596	1,010	680	0·001 mg.	15 days (died)	Small caseous ulcer; nearest glands normal; there was one translucent tubercle in the lungs.

Virus B. V. (G.P. 711).

Rabbits Inoculated with Culture grown for 743 Days on Pure Serum and 166 Days on Glycerin Media.

The subculture used was the 21st generation, 21 days old, and was grown on ox serum.

The total age of the culture was 809 days.

All the inoculations were made intravenously.

Number of Rabbit.	Initial weight in grammes.	Final weight in grammes.	Dose.	Duration of Life.	Result.
790	1,300	950	1·0 mg.	15 days (died)	Lungs collapsed fairly well and contained numerous discrete grey tubercles, the largest the size of a millet seed; the bronchial glands showed opaque caseous foci in the cortex; spleen enlarged, firm, peppered with minute grey foci; there were a few grey points just visible in the liver and one or two minute foci in each kidney; a few opaque foci in cortex of portal and lumbar glands.
791	1,550	910	0·1 mg.	21 days (died)	Lungs crepitant but a little fuller than normal; they contained fairly numerous miliary caseating tubercles; the bronchial glands contained caseous nodules; spleen enlarged, firm and dark red, closely beset with minute yellowish foci; liver speckled throughout with minute grey foci; moderately numerous caseating tubercles in the kidneys; minute caseous tubercles in most of the lymphatic glands.
792	1,750	1,320	0·01 mg.	62 days (died)	The lungs were enlarged, firm, and composed for the most part of grey translucent tissue with an irregular caseous network. Spleen slightly enlarged, contained moderately numerous discrete yellow tubercles; in the cortex of each kidney were numerous grey tubercles, with caseous centres, many of which extended towards the pelvis as radial streaks; liver appeared normal; cortex of portal gland partly caseous; most other lymphatic glands contained caseous tubercles; scattered about the muscles were moderately numerous yellow tubercles up to a pin head in size.
793	1,200	1,000	0·001 mg.	52 days (died)	Lungs were pinkish and crepitant and contained sparsely scattered caseous tubercles, up to 2 mm. in diameter, with grey margins; they were irregular in outline and situated chiefly just under the pleura; the bronchial glands showed a few opaque foci; the mediastinal were partly caseous; there was some turbid fluid in the peritoneal cavity; spleen enlarged, firm and closely beset with irregular greyish white foci, here and there aggregated together; the liver showed numerous minute grey foci and grey submiliary tubercles; kidneys appeared normal; several lymphatic glands contained caseous tubercles.

REPORT ON THE STABILITY OF VIRULENCE OF THE TUBERCLE BACILLUS OF HUMAN ORIGIN IN ARTIFICIAL CULTURE, INCLUDING THE INFLUENCE OF GLYCERIN IN CULTURE MEDIA.

Dr. L. COBBETT.

THE STABILITY OF VIRULENCE OF THE TUBERCLE BACILLUS IN ARTIFICIAL CULTURE.

The Virulence of Tubercle Bacilli from Cultures and in Emulsions of Tuberculous Animal Tissues compared.

It has been repeatedly observed, both here and at Walpole, that to produce tuberculosis of a given severity in an animal a much larger number of tubercle bacilli are required when these are obtained from a culture, even a young one, than when they are contained in an emulsion of tuberculous tissue from an infected animal. Dose for dose, estimated in numbers of tubercle bacilli, cultures are decidedly less virulent than emulsions of tuberculous tissue*. It is difficult to say whether this is because cultures contain a larger proportion of dead bacilli, whether tuberculous tissues contain poisons which cultures do not, whether the tissue matter acts mechanically and protects the bacilli from the attack of the defensive forces of the body, or whether an attenuation of the bacilli takes place when they are transferred from their natural habitat to our artificial culture media.

If the last of these be the true explanation, then one would expect the attenuation to be not altogether sudden and complete, but to extend over the earlier period of cultivation for perhaps several weeks, so that it should be possible to demonstrate the attenuation by comparing the virulence of very early cultures with others which had been growing for a longer period.

No direct experiments of this kind have been made, but seeing that our viruses of Group I. differ in virulence from one another so little that the difference has not been demonstrated by our experiments (H 49, T.C. excepted), it is possible to compare the virulence of recently isolated strains of culture of one virus with those of another which have been longer in cultivation. For this purpose several strains have been raised as quickly as possible, and bacilli from cultures three weeks old have been injected within 5, 7, or 8 weeks of the time when the virus was first sown on artificial media. These can be compared with other strains which have been several years under artificial cultivation.

This comparison is, of course, not an exact one, for not only were different viruses employed, but the calves were not of precisely the same size, and differed much, as we know, in individual susceptibility. Yet the results are very fairly uniform, and had any considerable attenuation taken place during the period of cultivation it could not have failed to make itself known.

* Experience here has shown that to produce a rapidly fatal tuberculosis in the calf by subcutaneous injection about 500,000,000 tubercle bacilli direct from an animal lesion are required, while, if cultures be used, 50 mg. is necessary, 10 mg. being not certainly fatal. (Compare the table of tissue emulsion injections with that of culture injections; Vol. II., Section II.) Since Dr. Eastwood estimates that 10 mg. contains 45,000,000,000 bacilli, the bacilli from recent tuberculous lesions in the animal (guinea-pig, calf, or rabbit) would appear to be equivalent to more than 100 times as many obtained from a young serum culture.

TABLE SHOWING THE RELATION OF THE TOTAL AGE OF CULTURE (time since isolation from animal during which the bacilli have grown in artificial cultivation on pure serum) TO VIRULENCE.

GROUP I. VIRUSES.

All Cultures injected were grown for 3 weeks.

DOSE: 50 MILLIGRAMMES.

Does Long-continued Cultivation on Artificial Media Attenuate the Tubercle Bacillus?

The evidence of attenuation during artificial cultivation afforded by the calves injected with 50 mg. of bacilli is of the slightest (*see* Table, page 188). The youngest strain, which had only been five weeks under cultivation when injected, killed a calf in almost the shortest period, namely, 21 days. One two months old killed as quickly. But another, cultivated for 20 months, killed even more rapidly, namely, in 20 days. One calf alone survived the period of observation. It had been injected with a strain which had been cultivated for 16½ months. Possibly all these were exceptional animals.

Twenty-eight calves were injected with bacilli from strains which had been less than a year in cultivation; all died or were in a dying condition when killed. Twelve were injected with bacilli from strains more than a year in cultivation; all died or were killed when dying, except the one which was in good condition when killed 90 days after injection. Counting the duration of life of this one as 90 days, the average duration of illness for the two groups works out at 34·6 and 39 days respectively. Strains which had been more than two years in cultivation killed in 40, 44, and 47 days.

Thus the evidence of this table is not opposed to a slight and slowly progressing attenuation.

Table showing the Relation of the Total Age of Culture (time since isolation from animal during which the bacilli have grown in artificial cultivation on pure serum) to Virulence.

Group I. Viruses.

All Cultures injected were grown for 3 weeks.

* After increase of virulence.

Among the calves injected with 10 mg. of bacilli about 1 in 4 survived for 90 days, and many of these were in good condition and had only a slight amount of tuberculosis when killed. It is perhaps significant that 9 of these less severely affected animals occurred among the 24 calves injected with strains which had been cultivated for more than a year, and two only among the 17 injected with strains which had been cultivated for less than a year.

But these calves were highly-resisting individuals, for their fellows, treated like themselvs, died of acute tuberculosis; it would not be reasonable to expect the exceptional individuals to be distributed equally among two such groups as we are considering. It may therefore be that a capricious distribution of animals of high resistance accounts for this evidence of attenuation.

If we leave out all the calves which survived 90 days, regarding them as exceptionally resistant individuals, and consider only those which died—though doubtless these also differed from one another in susceptibility—we find that of 15 animals injected with strains which had been less, and 15 with strains over a year in artificial cultivation, the average duration of illness was 42·3 and 46·5 days respectively. Here again the evidence is in favour of a slowly progressing attenuation.

* After increase of virulence.

The analysis of the rabbit injections gives no evidence of attenuation during cultivation.

Summary.

Both tables of calf injections agree together in showing that strains of bacilli which have been long in cultivation are slightly less virulent than those which have been more recently isolated. The number of animals is probably too great to admit of this agreement being merely accidental. We must, therefore, conclude that a slowly progressing attenuation does take place during long continued cultivation. But the striking fact shown by these tables is not the evidence of attenuation, but on the contrary, the slightness of this evidence, which strongly testifies to the remarkable stability of virulence [as compared with some other micro-organisms] of the tubercle bacillus, which hardly becomes appreciably attenuated after several years cultivation. There is no evidence that attenuation is more rapid in the early days of cultivation than it is at a later period. The analysis, therefore, lends no support to the view that bacilli from cultures are *intrinsically* less virulent than those from tissue emulsions.

THE INFLUENCE OF GLYCERIN IN CULTURE MEDIA.

All the experiments already considered in this Report were made with cultures on pure serum. It has been suggested that glycerin in culture media may attenuate tubercle bacilli. This is of importance because some of our Group II. viruses have been injected after growing on glycerin-serum, and this medium has been largely used by me for separating mixtures of eugonic and dysgonic tubercle bacilli, or for attempting such separation from strains which came under suspicion. It was there desirable to investigate whether glycerin in culture media has any attenuating action

Two questions presented themselves—

(1) If two cultures be sown, from a stock hitherto grown on pure serum, on serum with and on serum without glycerin, will there be any difference in the severity of the illness caused by injecting them into animals in equal quantities ?

(2) Does long-continued cultivation on glycerin-media attenuate ?

In order to answer these questions many animals were injected in pairs, one of each pair with a culture grown on serum and the other with one grown on 5 per cent. glycerin-serum

Calf Injections.

In the case of only one virus of Group I., H 7, "C.M.," have comparative injections been made on calves. In that case there was no appreciable difference in the result. Four non-virulent strains were injected, for the purpose, as already described, of controlling those calf injections which have already been made with non-virulent cultures. They show no appreciable difference in the result, whether cultures on pure serum or on serum with 5 per cent. of glycerin were used.

Rabbit Injections.

A much larger number of comparative injections with viruses of Group II. have been made on rabbits. These also show no appreciable difference in pathogenicity between cultures grown on pure serum and those on glycerin-serum. For the sake of brevity the table is omitted.

Comparative injections have been made on rabbits with eleven strains (ten viruses) of bacilli of Group I.

In some cases where life was much prolonged the cause has been found in the fact that the injection was not really intraperitoneal, but only partly intraperitoneal and partly intramuscular, or intracœcal. Omitting these spoilt experiments, there is a clear consensus of evidence that pure serum cultures kill quicker than those on glycerin-serum. The difference is not great, but is fairly constant (with a few exceptions, easily explicable on the hypothesis of variations in individual susceptibility).

S. = Pure serum cultures. G.S. = Cultures on serum + 5 per cent. of glycerin. † After increase of virulence.

The numbers in the columns headed "S" represent the duration of life in days of rabbits injected with different doses of serum cultures; the opposite numbers in the columns headed "G.S." represents the duration of life of rabbits injected with similar doses of glycerin-serum cultures. The average duration of life of the rabbits inoculated with serum and glycerin-serum cultures respectively in each of the four doses used is also shown.

All those animals in which the tuberculosis was seriously complicated by other disease, or in which there was evidence that the injection had not been entirely intraperitonal, are omitted. This accounts for the gaps in the analysis.

The difference between the virulence of the serum and the glycerin-serum cultures is greater with some viruses than with others. Thus, it is great in the case of H 38 "J.M.," and H 19 "S.W.," which are less dysgonic, while it is least in the very dysgonic viruses, H 10 "B.S.," H 14 "F.S.," and H 16 "J.H." (fourth passage).

GUINEA-PIG INJECTIONS.

Comparative injections with cultures on glycerin-serum and pure serum have been made upon guinea-pigs also. Three viruses of Group I. and three of Group II. were employed for this purpose. The results are given in the following tables.

0·1	23 & 27	28 & 28	31 & 29	31	27	31 & 34	**27·4**	**30·4**

S. = Pure serum cultures. G.S. = Cultures on serum + 5 per cent. of glycerin. * After increase of virulence.

The numbers in the columns headed "S" represent the duration of life in days of guinea-pigs injected with different doses of serum cultures; the opposite numbers in the columns headed "G.S." represent the duration of life of guinea-pigs injected with similar doses of glycerin-serum cultures. The average duration of life of the guinea-pigs inoculated with serum and glycerin serum cultures respectively in each of the two doses used is also shown. All those animals in which the tuberculosis was seriously complicated by other disease, or in which there was evidence that the injection had not been entirely intraperitoneal, are omitted from the analysis.

In these experiments, as in those with the rabbits, the serum cultures were on the whole a little more rapidly fatal than those on glycerin-serum. This difference is equally marked with the viruses of the two groups.

The difference in the duration of the disease caused by serum and glycerin-serum cultures respectively, both in rabbits and guinea-pigs, is not constant, but the longer survival of the animals injected with glycerin-serum cultures occurred too frequently to be altogether the result of accident, and one must therefore conclude that the injection of bacilli grown upon serum cultures causes a slightly more severe disease than that produced by bacilli from glycerin-serum cultures. The difference, however, is too slight to materially affect the results of the experiments made to ascertain the virulence of our viruses.

Does long-continued Cultivation on Glycerin Media attenuate?

Having shown that glycerin-serum cultures are slightly less virulent than serum cultures, the next point to consider is whether the difference in virulence is due to a difference in the chemical products formed in the two media, or whether it is a true attenuation. If the latter, one would expect attenuation to be progressive, that is, to become more marked the longer the culture was kept on glycerin-serum, and one would not expect any return of virulence if the culture were resown on pure serum. If, however, the difference in virulence be due to a difference in the chemical products of bacterial growth on the two media, one would not expect any further change of virulence after the first glycerin-serum culture, as long as the strain remained on that medium, but one would expect a return of virulence if the strain was again grown upon pure serum.

Experiment with the Virus H 10, "B.S."

With the object of investigating these points, a virulent strain of culture was taken, and a series of cultures started on glycerin-serum.

The glycerin-serum cultures were resown every three weeks, and on every alternate occasion of sowing cultures were also sown on pure serum from the last of the glycerin-serum series. Thus one obtained a series of cultures on glycerin-serum, and another on pure serum after growth for three, five, seven and nine generations on glycerin-serum. The latter were injected, when three weeks old, in measured doses, into rabbits, as were also the first and last cultures of the glycerin series. The strain was grown on glycerin-serum for ten generations and during a period of eight months.

The strain used was that belonging to Virus H.10. "B.S.," and had been obtained from a guinea-pig injected from Calf 113. It had been already grown for thirteen generations on pure serum.

ANALYSIS OF THE RESULTS OBTAINED WITH THE VIRUS H 10. "B.S."

Dose in Milligrammes.	Serum Culture Control.	2nd Culture on Glycerin-Serum.	Serum Cultures after 3, 5, 7, and 9 generations on Glycerin-Serum.				10th Culture on Glycerin Serum.
			3	5	7	9	
10	21	17	–	–	19 and 17	–	16
1·	23	–	28	53 and 21	24 and 28	29	21
0·1	44	26	–	–	–	29	25
0·01	78	–	–	–	–	–	–

In the analysis of the preceding table the animals are arranged in transverse lines according to doses. The numbers represent the duration of illness (in days). Therefore, if there were any attenuation, the duration of illness should increase as any given line was read from left to right.

The experiment shows that even after having been grown for ten generations on glycerin-serum, and during a period of 8 months, there was no increase in the duration of illness and therefore no attenuation. All those animals in which the tuberculosis was seriously complicated by other disease, or in which there was evidence that the injection had not been entirely intraperitoneal, are omitted. This accounts for the gaps in the analysis.

EXPERIMENT WITH THE VIRUS H 7. "C.M."

A similar experiment was made with the virus H.7, "C.M." It differs from the foregoing in the following particulars. Each culture of the glycerin series was injected into rabbits, and from it a pure serum culture was made, and this also was injected into rabbits. Thus we have a double series of rabbit injections, one with cultures on glycerin-serum, and the other with cultures on pure serum, each after a longer or shorter period of growth upon glycerin-serum.

The strain used for this experiment was that obtained from Calf 5 through Guinea-pig 448, and the series of glycerin-serum cultures was commenced from the 15th culture on pure serum.

VIRUS H. 7 "C.M."

GLYCERIN-SERUM CULTURES.

Dose.	Generation of Culture on Glycerin Serum.						Average.
	1st.	2nd.	3rd.	4th.	5th.	6th.	
10 mg.	25	12	37	–	25	17	23·2 days.
1 mg.	37	31	–	21	30	19	27·6 „
0·1 mg.	–	33	52	77	49	–	52·7 „
0·01 mg.	94	47	98	–	–	–	79·7 „

The analysis is arranged like the last. All cases complicated by severe psorospermosis or other intercurrent disease are omitted.

It will be observed that the difference in duration of illness between the rabbits which received glycerin-serum and those which received pure serum cultures is far more marked in those which received 10 mg. doses than in those which received smaller quantities. This in itself is in favour of the difference being due to a difference in toxic products. But further it will be seen that no *progressive* diminution of virulence occurred on glycerin-serum and that the serum cultures which were sown from the series of glycerin-serum cultures were as virulent as the original ones which were sown from the strain which had always grown on pure serum.

EXPERIMENT WITH THE VIRUS H 28 'C.L."

If any further evidence is needed to show that glycerin in the culture medium does not attenuate, it is afforded by an experiment with the virus H.28, "C.L." A strain derived from human cervical glands through rabbit 102 was sown on serum and glycerin-serum, and parallel series of cultures on these media were kept growing for over a year. At the end of this period serum cultures were sown from both, and calves and rabbits injected with them. Each strain was injected into two calves in doses of 10 mg. One of these animals unfortunately was found at death to be suffering from obstruction of the ureters. This somewhat interferes with the comparison but it may be stated that each strain proved fatal to one calf, and caused but slight tuberculosis in the other.

In the case of the rabbits the serum culture from the glycerin-serum series actually killed three out of four animals a little quicker than did that sown from the serum series; but this was doubtless a coincidence. One may, however, conclude that the experiment afforded no evidence whatever of the supposed attenuating power of glycerin.

SUMMARY.

There can, I think, be no doubt that when grown on pure serum, cultures of viruses belonging to Group I. on the whole prove rather more rapidly fatal to rabbits and guinea-pigs than when they have been grown on serum with glycerin. The difference is most marked with large doses. It is neither progressive nor permanent; strains grown for months or a year on glycerin-serum are no less virulent than the same strain sown for one generation only on that medium. Transference to pure serum restores the original virulence. Therefore, one must conclude that glycerin causes no true attenuation of the bacilli; and that the reason that, dose for dose, serum cultures are a little more rapidly fatal than glycerin-serum cultures is, in all probability, because the latter are deficient in some toxic product which is present in the former.

Note.—G.T. = General Tuberculosis.

REPORT ON THE MINUTE NON-PROGRESSIVE TUBERCLES FOUND IN CALVES INJECTED WITH TUBERCLE BACILLI OF HUMAN ORIGIN WHICH ARE UNABLE TO PROVOKE A PROGRESSIVE INFECTION IN THIS SPECIES OF ANIMAL.

Dr. L. COBBETT.

BLYTHWOOD

REPORT ON THE MINUTE NON-PROGRESSIVE TUBERCLES FOUND IN CALVES INJECTED WITH TUBERCLE BACILLI WHICH ARE UNABLE TO PROVOKE A PROGRESSIVE INFECTION IN THIS SPECIES OF ANIMAL.

In addition to the lesions* constantly found in calves subcutaneously injected with viruses of human group ii, namely, those incapable of causing progressive tuberculosis in these animals there were found on close inspection often one or more, rarely many, minute tubercular foci in the larger viscera or in the lymphatic glands.

In this Report these little tubercles are described, and their incidence among the injected calves is analysed with the object of elucidating their significance. Two questions present themselves :

(1) Are they characteristic of certain viruses, which are thus shown to be of somewhat higher virulence than other viruses which do not produce them ?

(2) Or if not, what determines their presence in some calves, and their absence from others ?

These minute tuberculous foci appeared in the lymphatic glands as opaque, ochre-coloured, calcareous points. They were usually few in number, but in one or two instances they were rather numerous. (*e.g.* in Calf 619, H. 12, H .N.).

Among the great organs they were most commonly found in the lungs, and there appeared as translucent grey points, darker than the surrounding tissue. They were often so small that they were not easily seen, and sometimes they were only found after the lungs had been allowed to dry a little. At most they were as large as a small pin's head. They were either entirely translucent, looking like little specks of glass, or they had a minute central opacity. They were hard, and could easily be picked out on the point of a knife where they appeared as sharply defined spherical bodies resembling little beads of glass, or rather transparent pearls. When crushed on a cover glass they could be distinctly felt to crack.

When these little bodies appeared in the liver or spleen, which they did but rarely, they were similar to those in the lung. Only they then appeared as pale bodies on a darker ground, owing, I suppose, merely to contrast.

They were usually few in number; often two or three only were found in a single organ; but sometimes they were more numerous, and in four instances they occurred in somewhat large numbers.

That these bodies were tuberculous in origin cannot be doubted, because tubercle bacilli were sometimes found in them. That they were not early tubercles capable of progressing there can equally be no doubt, for they were found months after injection in calves which were obviously doing well, and had long ago recovered from any disturbance of health caused by the injection. Histological examination has shown that they were not in an active stage of formation; and there can be no doubt that they were tubercles which had very early commenced to retrogress.

This was not at first clearly recognised, and in one or two calves in which they occurred in relatively large numbers, notably in Calf 365, H. 23, J.P., Calves 165 and 405, H. 18, T.T., and Calf 185, H. 9., C.T., they were mistaken for progressive tubercles in an early stage. Further experience during the last two years has convinced me that I was in error in so thinking, and a recent examination of the preserved specimens has shown how very minute the lesions were in even the more severe cases.

(*) These consisted of a caseous and softened local lesion enclosed in a fibrous capsule, and of calcareous nodules in the nearest lympathic glands ; often of nothing more. These caseous abscesses often ulcerated through the skin and discharged their content. The latter must have often been swallowed by the calves, and yet lesions attributable to this cause were seldom seen. The lesions in Calves 473 and 481, H. 30, E.M., may have had this origin.

These four calves are therefore now regarded by me as showing in their organs the minute lesions of retrogressive type, so frequently seen in calves injected with viruses which are not capable of causing in them a progressive tuberculosis, and only exceptional in possessing them in unusual numbers.

The origin of these little tubercles seems to be attributable to bacilli which passively escape from the seat of subcutaneous injection. For the evidence of this the report on the distribution of non-virulent tubercle bacilli in the body of the calf after subcutaneous injection may be consulted [*See* p. 219]. In that Report it is shown that after subcutaneous injection, even of viruses incapable of causing a progressive infection, tubercle bacilli get distributed all over the body, and that, as a rule, they disappear without leaving any sign of their former presence. Occasionally, however, the minute translucent foci are found three months after injection, and may even then contain a few tubercle bacilli.

These little tubercles are evidence that the disease has made some amount of progress at a number of foci distant from the seat of injection, however completely that progress may have ceased before the animal came to be examined. The question then may be put thus : Is this short-lived development of tubercles in glands and organs rendered possible by any special quality of virulence on the part of the bacilli, or by some peculiar susceptibility of the individual animals in which they appear ? If the former, then one would expect these little tubercles to occur after the injection of certain viruses rather than of others. If the latter then one would expect the calves in which they occur to be distributed equally among all the feebly virulent viruses ; or rather as equally as the laws of probability will allow.

To answer this question then one needs to know whether any of the feebly virulent viruses are conspicuous among others for their power to cause these little tubercles, or whether all feebly-virulent viruses alike are liable to produce them. Accordingly a table has been drawn up including all the calves which have up to the present time shown these lesions, and a list giving for each virus the proportion of animals so affected to the total number injected subcutaneously with it.

In the table the tubercles in the organs are distinguished from those in the glands, and among the latter, the thoracic, mesenteric, and other lymph glands distant from the seat of injection are recorded separately. Moreover, the numbers of tubercles in each of these groups is roughly indicated : thus two or three or very few such foci are indicated by a single x, moderate and large numbers by x x and x x x respectively.

The table shows that these little tubercles have occurred in one or more of these situations and in larger or smaller numbers in nearly half the calves injected subcutaneously with viruses of group ii, and that these calves are widely distributed. All the viruses which have never produced progressive tuberculosis in bovine animals have caused these lesions, with the exception of seven (out of thirty-one). With each of these no more than two calves were used ; when larger numbers were injected with one virus some have always been affected, and the ratio of these to those which escaped is remarkably constant.

If we separate the viruses according to their seat of origin in the human being we find that no category is particularly distinguished for producing them, and that instances in which they were especially numerous occur among the lung, mesenteric gland, and joint viruses.

On the other hand it is only right to point out that the incidence of these little tubercles is rather greater among the calves injected with cervical and mesenteric gland

viruses than among those injected with lung or joint viruses; and these latter, it will be remembered, have, unlike the former, never yet yielded one virulent for cattle. But the difference is but slight (41 and 42·4 as compared with 50 per cent.), and it may be doubted whether this is more than accidental. On the whole, then, the conclusion seems justified that these little tubercles are not evidence of a superior grade of virulence in the virus that produced them.

The next question is: Why do these little tubercles occur in some animals and not in others injected with the same virus? The explanations which suggest themselves, namely, variations of dose, and individual susceptibility, and some accidental peculiarity of the mode of injection, will now be considered.

Dose we may dismiss at once, because the lesions have been caused by all kinds of doses, having followed such small ones as 13,000 and 10,000 bacilli in the case of H. 16 "J.H." and H. 12 "H.N." and having been absent after such colossal doses as 5,000 million (H. 16 "J.H"), 3,000 million (H 12 "H.N."), as well as 10,000 and 5,000 million (H. 26 "K.M."), and 5,000 million (H. 8 "S.C.").

As to individual susceptibility, there can, I think, be no doubt that great differences occur among calves. Of this there is a large amount of evidence, and I will only mention now the results of the 10 m.g. culture injections, which, in the case of two calves injected with the same virus, have often proved rapidly fatal to one, and left the other to live out its three months, without serious illness, and with a very moderate amount of disease at the end of this period. These injections were made with virulent viruses, but it seems reasonable to suppose that the same differences of susceptibility would come into play in the case of the feebly-virulent viruses also. (*)

But while differences of individual susceptibility appear as the most probable explanation of these little tubercles, I think I ought to point out that there are differences also in the circumstances of subcutaneous injections which may be not without influence. The possibility of some of the material entering a vein at the moment of injection cannot be seriously entertained. I desire rather to refer to differences which depend on the exact depth of the injection. Thus on occasions the injection has been made partly into the muscle, and even when this is not the case, differences in the plane of subcutaneous connective tissue into which the fluid enters may cause great differences in the amount of tension to which it is subjected. Thus, for example, at times one experiences a good deal of resistance to the entry of fluid, and in such cases the little swelling which results is prominent, circumscribed, and very tense; at other times there is little or no resistance and the swelling is flat and soft. Again the fluid may run up a considerable distance from the point of the needle, forming an elongated cord-like swelling. This happens, I think, when the needle enters the sheath of the subjacent muscle. In these varying circumstances it does not seem unreasonable to think that the difference of tension, at least, may make some difference to the passive absorption and consequent dissemination of tubercle bacilli.

However this may be, it seems obvious that each of these little tubercles must develop at a spot where a considerable number of tubercle bacilli have become arrested, for the report, on the distribution of bacilli already referred to, made it clear that the little tubercles by no means always develop wherever the bacilli have wandered to. Considerable numbers of bacilli at a single spot seem only explicable on the hypothesis that a phagocyte with a large cargo of them had run aground there. Probably wherever isolated bacilli, or small groups are arrested they are destroyed. But in the case of these larger aggregations some development of new tissue (tubercle formation), takes place before the invaders are destroyed. Thus the existence of these tubercles would appear to depend upon the presence of overloaded phagocytes, together with the inability of the animal to promptly destroy the bacilli. Whatever be the significance of the former, the latter is the result of some defect of the protective functions of the body. But it is hard to say which is the dominant factor.

LOUIS COBBETT.

(*) A fuller statement of the evidence of differences of individual susceptibility will be found in the Report on the influence of (i) the variation in the capacity for resistance to tuberculosis of different individual animals, and (ii) the number of tubercle bacilli injected, on the severity of an experimental infection [*See* p. 247].

REPORT ON THE DISTRIBUTION OF NON-VIRULENT TUBERCLE BACILLI OF HUMAN ORIGIN IN THE BODY OF THE CALF AFTER SUBCUTANEOUS INJECTION.

Dr. L. COBBETT.

REPORT ON THE DISTRIBUTION OF NON-VIRULENT TUBERCLE BACILLI IN THE BODY OF THE CALF AFTER SUBCUTANEOUS INJECTION.

The dissemination of a disease such as tuberculosis throughout the body from a focus of infection has generally been pictured as an active invasion by the micro-organisms, which in virtue of their virulence break down step by step the successive barriers which are raised against them. This report produces evidence of another kind of dissemination, and describes a passive escape of non-virulent tubercle bacilli from the seat of a subcutaneous injection in the calf, occurring very shortly after that injection, and a wide distribution of the bacilli throughout the body, followed either by their complete disappearance, or by minute lesions only which show no tendency to progress.

These minute lesions have been described in the preceding report, and I need not say more here than that they were either fibrous and very translucent, or calcareous, and so small as to be easily overlooked. They were therefore undoubtedly retrogressive.

Now, these little tubercles, occurring from time to time in the organs of calves which were obviously doing well, were a source of perplexity to me, for I could not understand how the bacilli could have got to these situations unless they possessed the virulence which should have enabled them to cause progressive lesions. Their presence conflicted with the belief that the severity of an infection caused by tubercle bacilli could be measured by the wideness of distribution of the lesions which they produced. For in these cases the distribution had obviously been wide and yet the disease had not progressed, the animals had recovered from any transient disturbance of health from which they once suffered, and had remained well, and grown normally.

Various hypotheses suggested themselves—the bacilli were perhaps in these cases of somewhat higher virulence than the average of the non-virulent class; or the animal exceptionally susceptible. But neither hypothesis reconciled the wideness of distribution with the arrest of progress. Either non-virulent bacilli had succeeded in distributing themselves over the body, or virulent bacilli had become arrested in their activity after they had succeeded in spreading themselves. If some sudden accession of resistent power were known to occur in tubercle as in pneumonia, this latter hypothesis would not have appeared improbable, but in tuberculosis such augmentation of resistance is unknown, and moreover other evidence showed that the viruses in question were of the ordinary non-virulent kind. Gradually it came to appear more and more probable that the dissemination of tubercle bacilli over the body in our experimental animals is not necessarily the active progressive invasion that it has been pictured, but might take place also by a passive absorption, which probably occurs before a barrier of granulation tissue has been built around the bacilli at the seat of injection, and that in the case of the bacilli injected being of feeble virulence for the animal, they either entirely disappear, or where most numerous cause evidence of their presence in a few little glassy or calcareous foci.*

It remained to put this theory to the test of experiment. Now it is obvious, if tubercle bacilli escape in numbers from the seat of injection, and after dissemination about the body disappear without causing any serious lesions, that one must expect the tubercle bacilli to be more numerous in the organs and tissues at some period not long after the injection than at the time when these animals are usually killed, namely three months later. This was actually found to be so in the case of Calf 769, which died of diarrhœa seventeen days after the subcutaneous injection of 50 mg. of a culture of the group II. virus H. 45, "F.M." At the post-mortem examination of this animal an inflammatory patch was found at the seat of injection, and the prescapular and prepectoral glands on the same side were swollen but showed no distinctive signs of tubercle. A scraping from each however, revealed numerous tubercle bacilli, while some were found also in the posterior-thoracic gland, which was normal in appearance. Four films from the lungs were searched but no tubercle bacilli seen. The full notes of the post-mortem examination of this and other calves mentioned here will be found on pages 229–233. At this stage I consulted with Dr. Eastwood, and asked him to co-operate with me in the investigation. To this he cordially agreed, and it was arranged that he should examine histologically the various tissues and organs of the calves while I injected tissue emulsions into guinea pigs. It was obvious that my part of the work could only be expected to show the presence or absence of bacilli in the tissues investigated, and would reveal but little as to their numbers; and it was hoped that the histological investigation would throw light on the method of dissemination which we expected to demonstrate, and by following the numbers of bacilli found in various organs of calves injected simultaneously and killed in succession, give valuable information as to the rise and fall of this dissemination of bacilli, and the relation between their escape from the seat of injection and the development of the local tumour.

Experiments with Virus H. 46.

At this time there happened to be two calves which had recently been injected subcutaneously with 50 mg. of the non-virulent virus H. 46, "H.W." (from a case of joint tuberculosis). In order to get to work as soon as possible it was decided to kill one of these animals about three weeks after injection, when the febrile reaction and the enlargement of the prescapular gland might be expected to be near their maximum, leaving the other as a control, to be killed and examined at the expiry of the usual three months interval.

The first of these calves, No. 767, was accordingly killed on May 23, 1905, twenty-five days after injection, while the second, No. 777, was killed on July 27, and their various organs and tissues were examined in the way agreed upon. Dr. Eastwood's report on this and the other calves which bear on the question under consideration will be found in Volume IV., pp. 13–19. It remains for me to describe the gross lesions of the calves, and the result of injecting the tissue emulsions into guinea-pigs, and as the former are fully given at the end of this report, and the latter clearly shown in the table which follows, it will be unnecessary to give any more than a brief description here.

These two calves, Nos. 767 and 777, had been subcutaneously injected with 50 mg. of three weeks' old serum culture on the right side of the neck on April 28th, 1905.

No. 767 was killed on May 23rd, twenty-five days after injection, when the febrile reaction was just over and the enlargement of the prescapular gland probably at its height. At the postmortem examination there was found a large flat tumour at the seat of injection, caseo-necrotic, and containing a large irregular cavity. It had not however begun to soften in its periphery. It was closely attached to the subjacent muscle and slightly infiltrated the skin. The right prescapular gland was enlarged and consisted partly of a grey translucent tissue and partly of a caseating network. The right prepectoral gland was slightly affected. On the surface of the lungs rather numerous minute translucent grey points could be seen. Some of these had a reddish tinge, and it was

* At one time one questioned whether in these cases some of the injected material might not have got into a torn vein at the moment of injection, but the repeated occurrence of such cases made this suggestion unthinkable.

difficult to distinguish them from the minute hæmorrhages which are of frequent occurrence, even in normal animals. Some were undoubtedly tubercles of the kind frequently found in these cases, for they could be picked out on the point of a knife. Scarcely any trace of opacity could be seen in the centres of any of them. In the liver and kidneys one or two pale specks on the surface were the nearest approach to tubercles which could be seen. All other parts appeared perfectly normal.

Emulsions were made from liver, spleen, lung, and rib marrow, all but the last being rich in tissue, and 1·0 cc. of each was injected into guinea-pigs. Table showing the results of these and similar inoculations will be found at the end of this report.

All the guinea-pigs were found to be tuberculous when killed seven weeks later. One alone, injected with marrow, had tuberculosis of the omental gland only, all the rest had general tuberculosis. There was obviously then a very wide distribution of tubercle bacilli in this calf, involving the bone marrow as well as the principal organs, far wider than the visible lesions would have led one to suppose.

The control Calf, No. 777, was killed ninety days after injection. The lesion at the seat of injection consisted of a fibrous walled cavity with fluid contents, and the prescapular gland on the same side contained two large fibro-calcareous nodules. In several of the mesenteric glands were some small calcareous foci. There was no visible trace of tubercle elsewhere, or vestige of the previous presence of bacilli, unless indeed some little areas of collapse in the lung were of this kind.

Guinea-pigs were injected with emulsions of the same parts as before, care being taken to inject even larger doses. The guinea pigs which received emulsions of spleen, liver, and rib marrow intraperitoneally were perfectly healthy when killed forty-two days later, while those injected with the lung emulsion were found to be tuberculous.

Experiment with Virus H. 26.

The next experiment was made with the virus H 26, "K.M." (obtained from a human kidney), which had proved itself non-virulent for calves and rabbits, and of which the enormous dose of 10,000 million bacilli had already been injected into a calf with only minimal results.

On July 25, 50 mg. of three weeks' old serum culture was injected into each of five calves subcutaneously on the right side of the neck.

No. 873 was killed *three* days later. There was a small soft swelling at the seat of injection, the subcutaneous tissue being a little thicker and firmer than normal, and the surrounding tissue a little œdematous. The prescapular gland on the same side was somewhat swollen and œdematous; everything else appeared perfectly normal.

Some 3 or 4 c.c. of blood from the left iliac vein were injected into a guinea pig, without producing tuberculosis. Tissue emulsions of spleen, liver, and lung, as well as of bone marrow and popliteal gland (taken as a representative of the peripheral lymphatic glands) caused tuberculosis in the guinea pig. Only in the case of the animal injected with the popliteal gland was the tuberculosis slight, in all others it was general. The doses were large, and the emulsions with the exception of that of the bone marrow were rich in tissue.

Calf 881 was killed *eight* days after the injection. There was a small swelling at the seat of injection chiefly caused by a thickening of the subcutaneous tissue, which was firm and grey and infiltrated with shot-sized spots of softened matter resembling muco-pus. The right prescapular gland was somewhat swollen, but showed no sign of tubercle. All other parts were normal.

The tissue emulsions of this calf which were injected into guinea pigs were more numerous than before, and a larger dose of blood was given. The only guinea pig which escaped tuberculosis was one of two which were injected with an emulsion of rib marrow, the other was tuberculous. That which received 11 c.c. of blood from the heart was found when killed to have six tubercles in its spleen. Those injected with emulsion of spleen, liver, lung, kidney, thoracic gland, and popliteal gland, all were found to have general tuberculosis. The emulsions, with the exception of that of the marrow, were rich in tissue, and large doses were given.

The third calf, No. 869, was killed *fourteen* days after injection. It had remained quite well, but its temperature had risen a little, (to 40·2°C.) on the 13th day. It had gained 9lbs. in weight.

At the seat of injection was a tumour which measured 4 × 3 × 1¼in. In its centre was an irregular cavity containing muco-purulent material around which was dense œdematous tissue; the subjacent muscle was not infiltrated, but the skin over the tumour was distinctly altered in appearance. The prescapular gland was considerably enlarged. It was firm, elastic and œdematous, but there was no appearance characteristic of tubercle. The prepectoral was as large as a large pea, very similar in appearance to the prescapular but yellower. All other organs and glands were normal in appearance.

Injections of tissue emulsions were made into guinea pigs as before. Between 2 and 3 c.c. of blood only was injected and this caused no infection. The rib marrow again infected one guinea pig only out of two; the spleen, liver, lung, kidney, long thoracic and popliteal glands caused general tuberculosis; the doses were large and the emulsions except that of the rib marrow rich in tissue as before.

The two remaining calves were killed three months after injection. No. 871 had developed a very large swelling and gland, and had been obviously ill a fortnight after the injection, with rapid respiration, staring coat, and high temperature lasting two or three weeks. Later on it became thin, but afterwards picked up, and gained 27 lbs. The average rate of gain during the whole period had been 2lbs. per week. It had been quite well for a month or more before it was killed.

At the seat of injection there was the thin-walled fluid tumour characteristic of a non-virulent injection. There was no infiltration of skin or muscle. The prescapular gland was a little enlarged and almost entirely occupied by a calcareous mass. The prepectoral was also enlarged and very similar in appearance. There were a good many little glassy tuberculous foci in the lungs, few of which had any central opacity, and two rather larger shot-sized tubercles. There were one or two very minute pale specks in each kidney. The suprarenals each contained one or two small tubercles. Minute calcareous foci were found in small numbers in the bronchial and other thoracic glands; the mesenteric, the left supra-pharyngeal and submaxillary, both precrural, popliteal, gluteal, and ischiatic glands. So wide a distribution of non-progressive tubercles is unusual, but other examples have occurred, for example, in 619, H. 12, "H.N."

Tissue emulsions were made and injected into guinea pigs as before. Those injected with blood (13cc). died in a few hours, and one of those injected with marrow died in two days. The rest were killed after fifty-three days (*see* table.) The second guinea-pig injected with marrow was healthy, as were those injected with kidney. Those injected with lungs, liver and spleen had tuberculosis more or less generalised, but in no case severe. These guinea pigs were less affected than those which received emulsions from the more recently affected calves. One may therefore conclude that the bacilli had disappeared from the marrow and kidney, but were still present, though in reduced numbers, in the lungs, liver and spleen. The presence of living non-virulent bacilli in the organs other than the lungs after three months must, I think, be regarded as exceptional, judging from Calf 777, "H.W.", and 865 "K.M." which follows, and remembering that the animal in question presented an unusual number of minute lesions visible to the naked eye.

Calf 865 was killed about the same time. It had been well almost ever since the injection, except for a transient disturbance of health about the third week, and a period of slight fever which lasted about a fortnight. Its average rate of gain during the whole period was 4 lbs. per week. The tumour at the seat of inoculation had softened, ulcerated, and discharged its contents.

At the seat of injection was found a little depressed opening in the skin, leading to a patch of dense brownish-pink tissue packed with little calcareous grains.

The prescapular gland on the same side was a little enlarged and contained some large calcareous nodules, one of which was commencing to soften. The right prepectoral was normal. In the mesenteric glands a little

yellow calcareous focus was found here and there; everything else was normal, unless indeed some little grey specks in the lungs were the legacy of the tubercle bacilli which had been there. They were more minute by far than the glassy tuberculous foci so often described, and they would not have been thought worthy of mention in any other case.

Tissue emulsions were made as before and injected into guinea pigs, care being taken that the doses should be larger than those used in the three first calves of this experiment. Those injected with blood (12cc.) died in a few hours. One guinea-pig injected with lung died after nine days and showed no signs of tuberculosis. One of those injected with popliteal gland died after fifty days, and was found to have general tuberculosis. The remaining guinea-pigs were killed on the 51st day. The one injected with lung was found to have slight tuberculosis, thus supporting the suspicion that the very minute grey specks seen in that organ at the post-mortem examination of the calf were tuberculous in origin. Those injected with spleen, liver, kidney, and rib marrow were found to be perfectly healthy. On the other hand all those injected with glands, namely the popliteal, long thoracic, bronchial and hepatic were tuberculous.

The presence of tubercle bacilli in some of the apparently healthy organs and glands of these two calves, and of Calf 777, which, it will be remembered, had been injected with a virus incapable of producing a progressive, and indeed anything more than a minimal tuberculosis in bovine animals, and which had recovered from any temporary illness from which they may have suffered when they were killed 3 months after injection, was surprising. It became clear that non-virulent tubercle bacilli which get passively disseminated after a subcutaneous injection do not entirely disappear within 3 months.

On the other hand a comparison of the distribution of bacilli in these animals with that in those killed a few days or weeks after injection will leave no doubt that bacilli so disseminated become less numerous as time goes on, and although they have not everywhere disappeared at the end of 3 months, they at least have done so from many parts of the body.

It has been said that one of the calves killed after three months suffered from an illness of unusual severity as compared with other animals injected with similar doses of viruses of Group II. It is possible, therefore, that the distribution of bacilli and their persistence in this animal was greater than usual; and it may be interesting to collect together in a table all the other guinea-pig injections made from time to time with the organs of bovine animals which had been injected with viruses of Group II. (*See* page 228.)

These injections were made for various purposes; some with the object of finding out whether a suspicious focus was tuberculous or no; some with the direct intention of ascertaining whether or no bacilli were to be found in apparently healthy organs; and others again—not always successfully—to demonstrate the non-tuberculous origin of some intercurrent disease, such as pneumonia, or carnification of the lung.

It will be seen that the presence of tubercle bacilli in these organs was by no means uncommon. Probably, however, the frequency is somewhat exaggerated by these experiments which were made, not in every case, but exceptionally for one of the reasons given above, consequently the animals from which the emulsions were taken are not quite fair samples of those injected with viruses not virulent for bovines, but were, some of them at least, selected on account of the presence of more or less suspicious foci, or for some other reason.

However, when one has made all due allowance for this, the findings of tubercle bacilli are still numerous, and one cannot doubt *that tubercle bacilli are frequently present in the organs and glands of bovine animals several months after they have been injected with bacilli which belong to the human Group II. Often they are contained in minute retrogressive tuberculous foci; but not unfrequently in organs which appear perfectly healthy to the naked eye.*

The negative result obtained in the case of the few experiments made with the organs of animals infected by feeding, seems to suggest that passive dissemination of bacilli does not take place in the absence of solution of continuity of tissue.

Summary and Conclusions.

The little glassy or calcareous tubercles often seen in the lungs, and more rarely in other organs of calves injected with tubercle bacilli which failed to produce in them a progressive infection, gradually led to the conviction that there must be *a passive* escape of tubercle bacilli into the circulation; for if they could only have made their way to these distant parts by *active invasion*, that is by overcoming the resistance offered to them by the animal organism, it seemed impossible to understand why they should then have failed to develop there. These experiments have revealed the presence of tubercle bacilli practically all over the body within three days of a subcutaneous injection of 50 mg. of a non-virulent culture, thus demonstrating the fact of passive distribution which had been inferred from the presence of these little glassy tubercles, and at the same time explaining their existence and showing that they afforded no evidence of virulence, and were in no sense due to the *active* invasion of the body by the bacilli which caused them.

It is not my intention to discuss the mode of dissemination, except to say that ultimately it must be by the blood. The very wideness of distribution points to this, and in one calf indeed, the blood from the heart itself infected a guinea-pig. Whether the escape of the bacilli from the seat of injection is by the lymphatic channels, and whether they are simply washed away in the stream of fluid, or carried by phagocytes are questions which fall rather into Dr. Eastwood's province than mine. But I should like to refer to one point which may be thought to have some bearing on the question, namely the difference between the local lesion produced by a virulent and that by a non-virulent virus. One of the characteristic features of the tumour caused at the seat of a subcutaneous injection in the calf by a virulent virus is that it widely infiltrates surrounding tissues, and innumerable caseous foci are found in the neighbouring skin, while the muscle often for a considerable distance contains caseous streaks and patches. On more than one occasion the lymphatics connecting the seat of injection in the neck with the nearest prescapular gland have been found thickened to the size of a small quill by a caseous deposit. On the other hand, if the virus is of the non-virulent kind the tumour after three months is sharply circumscribed and encased in a fibrous capsule often of considerable thickness, and with this capsule it can be easily dissected away from surrounding structures. One cannot but be reminded of the similar difference between a malignant and a benign tumour.

There seems no reason to doubt that the infiltration in the former case takes place by that process of active invasion which was alluded to at the opening of this report, and the fact that in the case of injection of *non-virulent* bacilli the tumour is sharply circumscribed seems to show that this *active* dissemination does not take place unless the virus is virulent, and that the little visceral lesions, which may follow the injection of a non-virulent virus, must be due to an absorption which is purely passive.

The passive distribution of tubercle bacilli from the seat of injection, appears to me to afford a reasonable explanation of the influence of dose in determining the severity of an infection caused by micro-organisms subcutaneously injected. For it is obvious that the numbers of bacilli *passively* distributed in the manner here described will depend largely upon the quantity injected. Whereas on the other hand, if they could only get out by a process of *active invasion* the numbers which thus gained access to distant parts would depend mainly on their activity or virulence, and but little on the original numbers injected; and yet we have repeatedly seen the injection of small numbers, even of very virulent bacilli, fail to cause a general infection.

It is not suggested that a dissemination of micro-organisms, comparable to what takes place when large doses of culture are *injected*, necessarily plays an important part in tuberculous, or other infections under natural conditions, when the number of invading bacilli must

necessarily be small. It is not my intention to discuss here the question, whether it ever plays any, and if so what part under these conditions. The interest of the observations recorded in this report lie, at the moment, in the light which they throw on the consequences of artificial infections such as are constantly being produced here. But the explanation which they offer of the occurrence of apparently isolated tuberculous lesions in distant parts, *e.g.* in the hip, will not be overlooked.

These emulsions, with the exception of that of the rib marrow, were very rich in tissue, the object being to inject as large a dose as possible.

From time to time during the course of the work here, guinea-pigs have been injected with emulsions of glands distant from the seat of injection and of organs of bovine animals which have been inoculated with the tubercular viruses of human Group II. Sometimes these have been made for the purpose of elucidating the nature of some suspicious focus; sometimes with the direct object of seeing whether the bacilli were to be found in the spleen or some other part, at others to demonstrate (not always successfully) the non-tubercular origin of intercurrent disease, such, for example, as pneumonia, or carnification of lung following an old blocking of a bronchus.

As these experiments add some additional evidence of passive dissemination to that already brought forward, they are collected together into the following table. As this kind of experiment was not made as a rule, but only for one of the reasons given above, it is probable that the calves from which the tissue emulsions came were not average samples of those injected with viruses non-virulent for bovines, but were on the whole taken from those rather more severely affected than their fellows, or from animals suffering from some other disease of more or less severity.

The frequency with which tubercle bacilli were found in these emulsions of organs then must not be taken as an exact measure of the frequency of passive dissemination in calves which have been subcutaneously injected. These experiments are only referred to here as additional evidence of the fact that such dissemination does occur.

It is a point of some interest that the animals fed with viruses of human Group II. afforded no evidence of passive dissemination though they developed some small amount of tuberculosis in the mesenteric glands. There is not enough evidence of this kind to warrant the drawing of any conclusions, but it would appear that passive dissemination does not occur unless the continuity of tissue is broken, as in subcutaneous injection.

EARLY DISSEMINATION OF TUBERCLE BACILLI IN A RAT.

In a rat, which received an intraperitoneal injection of culture from human spleen "H. 54, C.W." on 4-10-05., and which died without ascertained cause thirteen days later, tubercle bacilli were found in large numbers on microscopic examination of the spleen and liver pulp. A few were found also in the lungs, but none in the kidney. There was no lesion visible to the naked eye, except in the omentum which was drawn up and contained opaque yellowish-white collections, which, however, seemed to consist chiefly of the material injected.

Calf 769 (H. 45, "F.M.").

SUBCUTANEOUS inoculation on right side of neck of culture derived from human bronchial glands, through Guinea-Pig 1,137.

DOSE.—50 milligrammes.

DATE OF INOCULATION.—April 19th, 1905.

Weights :—

April 19th, 1905.—1 cwt. 0 qrs. 5 lbs.
May 6th, 1905.—0 cwt. 3 qrs. 10 lbs.
Total loss of weight :—23 lbs.

DIED of diarrhœa, May 6th, 1905 (17 days after inoculation).

POST-MORTEM EXAMINATION.

General Condition.—Very thin.

Seat of Inoculation.—At the seat of inoculation, on the right side of the neck, is a patch, 2½in. x 2in., composed of inflammatory tissue, soft and commencing to break down.

Right Prescapular Gland } Are slightly swollen, but
Right Prepectoral Gland } show no sign of tubercle.

Thoracic Glands.—Show no sign of tubercle.

Lungs.—Several dark points are seen, one of which only has a minute opaque centre. Of the rest, two, reddish and slightly raised, are situated on the visceral pleura. The lungs show superficial congestion about their bases.

Scraping from Long Thoracic Gland Tubercle bacilli few.

COMMENT ON CALF 769. H 45. "F.M." May 6th, 1905.

"This calf suffered for some time from, and ultimately succumbed to, diarrhœa. At the post-mortem examination the tubercular disease was found circumscribed as usual when viruses of the non-virulent kind are injected. The new fact revealed by this case was the considerable number of bacilli in the prescapular, prepectoral, and long thoracic glands. The two former were somewhat swollen, but showed no naked eye changes characteristic of tubercle, while the latter was normal in size. These bacilli were found then in a general scraping of the gland, while in ordinary cases, even when tubercular lesions are found in the thoracic glands, tubercle bacilli are limited to the visibly affected areas, and are even so very scanty. There were therefore in this case a much larger number of bacilli in the long thoracic gland than usual, and the question arises whether the tuberculosis was making a more severe progress in this case than usual on account of the intermittent disease, or whether a similar distribution of bacilli occurs in other cases, followed by their subsequent disappearance. The former hypothesis is not supported by other cases, where intercurrent disease has existed, while the latter is in harmony with the finding of minute arrested tubercles in small numbers in some of the animals injected with non-virulent viruses.

Calf 767 (H. 46, "H.W.").

SUBCUTANEOUS inoculation on right side of neck of culture derived from Guinea-pig 1444, inoculated with emulsion of tuberculous human knee joint.

DOSE.—50 Milligrammes.

DATE OF INOCULATION.—April 28th, 1905.

Weights :—

April 28th, 1905.—1 cwt. 0 qrs. 15 lbs.
May 23rd, 1905.—1 cwt. 0 qrs. 18 lbs.
Total gain of weight : 3 lbs.

KILLED.—May 23rd, 1905 (25 days after inoculation), at a time when the febrile reaction was just over, and the enlargement of the prescapular gland probably at its height.

POST-MORTEM EXAMINATION.

General Condition.—Good.

Seat of Inoculation.—The tumour at the seat of inoculation, on the right side of the neck, is large, flat, and fluctuating. It measures 6 in. x 3½ in. It is closely attached to the subjacent muscle, and slightly infiltrates the skin.

On section it is composed of caseo-necrotic tissue, and has large ragged cavity in its centre, full of caseous flakes suspended in a serous fluid.

Right Prescapular Gland.—Measures 3 in. x 1½ in. x 1¾ in. It is firm and elastic, and consists partly of translucent grey tissue, and partly of a caseating network. Its capsule is much thickened, and it is very adherent to the surrounding tissues.

Right Prepectoral Gland.—The size of a large pea, is firmer than normal, and in part of its cortex numerous yellow points could be faintly seen.

Thoracic Glands.—Normal.

Lungs.—On the surface of the lungs rather numerous minute grey translucent points can be seen. Some of these have a reddish tinge, and it is difficult to distinguish them from the minute hæmorrhages, which are of frequent occurrence. Some are undoubtedly tubercles, of the kind frequently found in these cases, for they can be picked out on the point of a knife. Scarcely any trace of opacity can be seen in the centres of any of them, and when crushed they do not break under the knife.

Pleura, *Heart*, *Omentum*, *Peritoneum* — Normal.

Liver.—One or two pale specks on the surface is the nearest suggestion of tubercles that can be seen.

Hepatic Glands, *Spleen* — Normal.

Kidneys.—A pale speck, similar to those seen in the liver, was seen in each kidney.

Suprarenals, *Tongue*, *Pharynx*, *Palate*, *Tonsils*, *Posterior Pharyngeal Lymphatic Glands*, *Submaxillary Lymphatic Glands*, *Hyoid Lymphatic Glands*, *Subparotid Lymphatic Glands*, *Intestines*, *Mesenteric Glands*, *Eyes*, *Testes* — Normal.

Various Lymphatic Glands:—
Left Prescapular, *Axillary*, *Precrural*, *Popliteal*, *Gluteal*, *Ischiatic*, *Renal*, *Lumbar*, *Iliac*, *Pubic* — Normal.

MICROSCOPIC EXAMINATION.

Focus from Lung.—No tubercle bacilli.

COMMENT ON CALF 767.

In some respects the local lesion and nearest gland resembled those found in cases of acute general tuberculosis, but the muscle, though adherent, was not infiltrated, as it invariably is in these latter cases, and the central cavity was much larger, showing a greater tendency to softening and breaking down. The lesions in the lungs were no more than are frequently seen in calves inoculated with non-virulent viruses, unless indeed there were rather more of them. They were very small, and, unlike those in calves killed ninety days after inoculation, they were not calcified.

In choosing this calf, one was influenced by the longer rise of temperature and by the larger size of the prescapular gland. But really there was little to choose between the animals, and the other had lost two pounds in weight, while the one killed had gained three. The remaining calf therefore is a fair control, and it must not be thought that the one killed was any more likely to develop general tuberculosis than the other.

Calf 777 (H. 46, "H.W.").

SUBCUTANEOUS inoculation on right side of neck of culture derived from Guinea-pig 1444, inoculated with emulsion of tuberculous human knee joint.

DOSE.—50 milligrammes.

DATE OF INOCULATION.—April 28th, 1905.

Weights,—
April 28th, 1905.—1 cwt. 0 qrs. 4 lbs.
July 27th, 1905.—1 cwt. 0 qrs. 6 lbs.
Total gain of weight.—2 lbs.

KILLED when in good health, July 27th, 1905. (90 days after inoculation.)

POST-MORTEM EXAMINATION.

General Condition.—Good.

At the Seat of Inoculation on the right side of the neck is a prominent fluctuating swelling measuring 4 x 2½ x 2in., and weighing 6½ ozs.

It consists of a fibrous walled cavity containing softened caseous débris.

There has been no external discharge.

Right Prescapular Gland is moderately enlarged, and contains two large fibro-calcareous nodules, the larger of which is already considerably softened.

Right Prepectoral Gland.—Not enlarged, is normal on section.

Lungs.—The lungs show several small areas of collapse, but are otherwise normal.

Thoracic Glands.—are not enlarged and are normal in structure.

Heart, *Pleura*, *Omentum and Peritoneum*, *Liver*, *Hepatic Glands*, *Spleen*, *Kidneys*, *Suprarenals*, *Tongue*, *Pharynx*, *Palate*, *Tonsils*, *Posterior-Pharyngeal, Submaxillary, Hyoid and Subparotid Lymphatic Glands* — Normal.

Mesenteric Glands.—The hooked mesenteric gland, which lies at the angle of the mesentery, contains many minute points visible throughout its capsule. These when picked out on the point of a knife and crushed between coverslips, are found to be slightly gritty. A few neighbouring glands also have some of these foci.

Small Intestine.—In the small intestine, about 1½ yards from the ileo-caecal valve, the part corresponding with the gland most affected, are seen a small number of whitish spots, quite superficial and easily scraped off

with a knife, unlike tubercles as usually seen. The large intestine is normal.

Testes.—Normal.

Various Lymphatic Glands:—

Axillary and Prescapular (left)
Precrural and Popliteal
Gluteal and Ischiatic
Renal
Lumbar
Iliac
Pubic
} Normal.

Microscopic Examination.

Foci from Mesenteric Gland.—Tubercle bacilli.

Foci from Small Intestine.—No tubercle bacilli.

Comment on Calf 777.

The minimal lesions usual when non-virulent viruses are injected were found in this animal.

This animal is the fellow to Calf 767, which was killed 25 days after inoculation in order that the various organs and tissues should be examined for tubercle bacilli. It therefore forms the control to the experiment just mentioned.

Calf 873 (H. 26, "K.M.").

Subcutaneous inoculation, on right side of neck, of culture derived from human kidney, through guinea-pig 1326.

Date of Inoculation.—July 25th, 1905.

Dose.—50 milligrammes.

Killed.—July 28th, 1905 (3 days after inoculation), in order to determine the distribution of bacilli at this period.

Post-mortem Examination.

General Condition.—Good.

Seat of Inoculation.—At the seat of inoculation, on the right side of the neck, is a small soft swelling. On section the tissues seem to be a little oedematous, and the subcutaneous tissue thickened and firmer than normal.

Right Prescapular Gland.—Is somewhat swollen and oedematous.

Calf 869 (H. 26, "K.M.").

Subcutaneous inoculation on right side of neck of Culture derived from human kidney, through Guinea-pig 1326.

Date of Inoculation.—July 25th, 1905.

Dose.—50 Milligrammes.

Weights.

July 25th, 1905.—0 cwt. 3 qrs. 0 lbs.
August 8th, 1905.—0 cwt. 3 qrs. 9 lbs.
Total gain of weight.—9 lbs.

Killed—When very well, in order to determine the distribution of bacilli, August 8, 1905 (14 days after inoculation).

Post-mortem Examination.

Seat of Inoculation.—At the seat of inoculation is a tumour, measuring 4″ x 3″ x 1¼″. At its centre is an irregular cavity, containing muco-purulent material, around which is dense oedematous tissue. The subjacent muscle is not infiltrated, but the skin over the tumour is distinctly altered in appearance.

Right Prescapular Gland.—Is enlarged (long axis three and a quarter inches), firm, elastic, and oedematous. There is no appearance characteristic of tubercle.

Prepectoral Gland.—Is the size of a large pea. It is very similar to the prescapular, but of a yellower colour.

Lung, *Thoracic Glands*, *Liver*, *Portal Glands* — Showed nothing abnormal.

Spleen, *Kidneys*, *Suprarenal*, *Testes*, *Intestine*, *Mesenteric Glands*, *Pharynx*, *Posterior-Pharyngeal Glands*, *All Peripheral Glands* — Normal.

Microscopic Examination.

Emulsion of Liver, *Emulsion of Lung*, *Emulsion of Kidney* — No tubercle bacilli seen.

Calf 871 (H. 26. "K.M.").

Subcutaneous inoculation, on right side of neck, of Culture derived from human kidney, through Guinea-pig 1326.

Date of Inoculation.—July 25, 1905.

Dose.—50 Milligrammes.

Weights.

July 25th, 1905.—0 cwt. 3 qrs. 19 lbs.
October 24th, 1905.—1 cwt. 0 qrs. 18 lbs.
Total gain of weight.—27 lbs.
Rate of gain per week.—2 lbs.

Killed.—When well, October 24th, 1905 (91 days after inoculation).

Post-mortem Examination.

Seat of Inoculation.—At the seat of inoculation is a large, rounded, fluctuating swelling, consisting of a fibrous wall and fluid contents, with caseo-necrotic masses of various sizes. At the posterior corner are some small calcareous nodules. It measures 3¾in. x 2⅛in. x 3 in., and weighs 9 ozs.

Prescapular Gland.—Measured 2⅛in. x 1⅝in. x 1in., and weighs 2 ozs. It was almost entirely occupied by a large and very calcareous mass, but a portion of the soft brown gland substance still remained.

Prepectoral Gland.—Was as large as a small cherry, and was also calcareous.

Bronchial Glands and Other Thoracic Glands — Were not enlarged. Here and there a small yellow calcareous focus could be found.

Lungs.—Looked quite healthy, but on close inspection a good many minute translucent glassy tubercles could be seen. The largest of these was only one millimetre in diameter. Few of them had any central opacity. In addition two rather large shot-like tubercles were seen.

Liver.—Normal.

Hepatic Glands.—Showed one or two little doubtful points.

Spleen.—Normal.

Kidneys.—Normal, except for one or two very minute pale specks.

Suprarenals.—Each contained one or two small tubercles.

Testes, *Tongue*, *Pharynx*, *Tonsils*, *Larynx* — Normal.

Intestines.—Normal, except for some pultaceous yellow points (with no tubercle bacilli).

Left Posterior Pharyngeal Gland.—Had two or three small calcareous grains.

Right Submaxillary Gland, *Right Post-Pharyngeal Gland*, *Hyoid Glands*, *Subparotid Glands* — Normal.

Mesenteric Glands.—Almost without exception contained little yellow calcareous grains.

The following peripheral glands contained a few little yellow calcareous grains:—

Precrural.
Popliteal.
Gluteal.
Ischiatic.

The following were normal:—

Iliac.
Axillary.
Renal.
Lumbar.

Microscopic Examination.

Calcareous Grains from the Popliteal Gland.—Tubercle bacilli few.

Calcareous Grains from the Long Thoracic Gland.—Tubercle bacilli. (Two seen.)

Glassy Tubercles from Lungs, *Larger Tubercle from Lung* — No tubercle bacilli.

Large and small Tubercles from Lung (mixed).—Tubercle bacilli few.

Emulsion of Spleen, *Emulsion of Liver*, *Emulsion of Rib Marrow*, *Yellow Pultaceous Matter from Intestine* — No tubercle bacilli.

Comment on Calf 871.

The animal developed a very large swelling and gland, and a fortnight after injection was obviously ill, with rapid respiration and staring coat. There was the usual rise of temperature, lasting two or three weeks. Later on it became thin, but afterwards picked up, and gained 27 lbs. It had been quite well for a month or more before it was killed.

The lesions seen were like those often before found in animals injected with non-virulent viruses. Thus there are numerous parallels to the lung lesions, and tubercles in the suprarenals have been fairly common, *e.g.*, 135, H.12, "H.N.," and many others.

To find a parallel to so wide a distribution of calcareous grains in the peripheral lymphatic glands one must go to 619, H.12, "H.N." 625, H.23, "J.P." The peculiarity of this calf is that it combines so many of these occasional lesions.

It is odd that while many peripheral glands were more or less affected, the renal and lumbar, which with virulent bacilli are usually more severely affected than the others, in this case escaped.

Calf 865 (H. 26. "K.M.").

Subcutaneous inoculation, on right side of neck, of Culture derived from human kidney, through guinea-pig 1326.

Date of Inoculation.—July 25th, 1905.

Comment on Calf 865.

Minimal lesions after 50 milligrammes of a feebly virulent virus.

The little grey points in the lungs would not have been thought worthy of notice if it were not considered that they might possibly be the legacy of the bacilli which escaped into the lung.

REPORT ON THE DISSEMINATION OF TUBERCLE BACILLI IN DIFFERENT SPECIES OF ANIMALS AFTER SUBCUTANEOUS INOCULATION.

Dr. **A. STANLEY GRIFFITH** and Dr. **F. GRIFFITH.**

ROYAL COMMISSION ON TUBERCULOSIS.

ON THE DISSEMINATION OF TUBERCLE BACILLI IN DIFFERENT SPECIES OF ANIMALS AFTER SUBCUTANEOUS INOCULATION.

It has been shown by Dr. Cobbett that slightly virulent tubercle bacilli are rapidly distributed throughout the body of a calf after subcutaneous inoculation, and can be demonstrated in the tissues by inoculating guinea-pigs.

The object of these experiments has been to ascertain whether a similar distribution takes place after subcutaneous inoculation of highly virulent tubercle bacilli, not only in the calf but also in other species of animals.

In five experiments bacilli of low bovine virulence were used.

Observations have been made on eight different species of animals, namely, the monkey, calf, pig, cat, rabbit, guinea-pig, rat and fowl.

The following table gives in brief the dose of culture and the duration of life in the case of each animal used in the investigation.

Species.	Number of Animals.	Dose of Culture.	Duration of Life.
Monkey - - -	1	20 mg.	24 hours.
Calf - - -	1	44 mg.	24 hours.
Pig - - - -	5	20 mg.	1, 3, 5, 8, and 14 days.
Cat - - - -	3	10 mg.	24 hours.
Rabbit - - -	3	20 (1) and 10 mg. (2)	24 (2) and 48 (1) hours.
Guinea-Pig - -	3	10 mg.	24 (2) and 48 (1) hours.
Rat - - - -	2	10 mg.	24 and 48 hours.
Chicken - - -	1	10 mg.	24 hours.

The subcutaneous tissues of the groin, back, or ear were chosen as the site of inoculation in order to obviate, during the removal of the organs, any possible chance of contamination by the culture inoculated.

The animals were killed by chloroform, and in every case blood was immediately withdrawn from the right ventricle by means of a glass pipette. A small quantity was distributed over the surface of each culture tube, while 2 cc., mixed with an equal amount of citrate of soda solution, were reserved for inoculating into a guinea-pig. The portions of the various organs from which cultures were made and guinea-pigs inoculated were removed with aseptic precautions.

The egg medium, which has been found the most reliable of all media for the production of primary cultures, was used exclusively, and the tubes were incubated for periods of two months.

The experiments show that tubercle bacilli are distributed over the body of an animal within 24 hours after subcutaneous inoculation, and this dissemination occurs in every species inoculated, whether the bacilli are virulent or only slightly virulent for that species.

That no inconsiderable number of bacilli escapes into the circulation is shown by the ease with which cultures were in all cases obtained from the spleen and by the production of tuberculosis in every guinea-pig inoculated with blood.

In the series of pigs killed at intervals the number of bacilli in the blood was greatest 24 hours after inoculation, and appeared gradually to diminish subsequently.

Seeing that in all species of animals the blood stream plays so important a part in the immediate distribution of tubercle bacilli over the body, the variations in the anatomical distribution of the disease which have been observed in different species after subcutaneous inoculation can best be explained on the hypothesis that different tissues vary in their susceptibility to tuberculosis.

It is interesting to observe in the case of the chicken the rapidity with which bacilli, which are incapable of setting up tuberculosis in that animal, are distributed over the body.

A. Stanley Griffith.

F. Griffith.

RHESUS MONKEY 150.

Inoculated subcutaneously between the shoulders on June 7, 1906, with 20 mg. of culture from the original material of Virus XXVI.

Killed June 8, 1906, 24 hours after inoculation.

PIG 146.

Inoculated subcutaneously under the skin of the ear on May 2, 1906, with 20 mg. of culture from Virus B.V.

Killed, May 5, 1906; 3 days after inoculation.

P.M.—In the subcutaneous tissues of the ear there was a yellow patch of necrosis, larger than in Pig 144, undergoing softening. The nearest lymphatic gland was slightly enlarged. There was no sign of disease in any other part of the body.

Distribution of Bacilli.

Material used.	Cultures.		Guinea-Pigs Inoculated (all Intraperitoneally).

Blood	2	None	1,995	Died, 23 days	Two or three minute transparent tubercles in omentum; pseudo-tuberculosis of spleen and liver. Microscopical. ? T.B. in omentum; none in liver or spleen.
Lung	—	—	1,998	Killed, 39 days	General tuberculosis.
			1,999	Died, 39 days	General tuberculosis.
Spleen	2	3	2,000	Died, 24 days	Numerous discrete tubercles in omentum; tuberculosis of spleen and liver and many glands. T.B. found in a splenic gland.
Liver	—	—	2,001	Died, 25 days	General tuberculosis. T.B. in the pyloric gland.
Muscle	—	—	1,996	Died, 39 days	Caseous nodule in muscle wall; a few tubercles in omentum and on peritoneum; slight tuberculosis of spleen, liver and lungs.
			1,997	Died, 24 days	The omentum contained four translucent miliary tubercles; no tuberculosis elsewhere. T.B. found in omental tubercle.
Marrow	—	1	—	—	—

PIG 148.

Inoculated subcutaneously under the skin of the ear on April 30, 1906, with 20 mg. of culture from Virus B. V.
Killed, May 5, 1906, 5 days after inoculation.

P.M.—In the subcutaneous tissues of the ear there was a small swelling composed of yellow necrotic breaking down substance. The nearest gland was enlarged and œdematous. There was no sign of disease elsewhere.

Distribution of Bacilli.

Material used.	Cultures.		Guinea-Pigs Inoculated (all Intraperitoneally).		
	Number of Tubes sown.	Number of Colonies observed.	Number of Guinea-Pig.	Duration of Life.	Result.
Blood - -	2	None	2,002	Died, 41 days	Small caseous nodule in muscle wall; nearest glands tuberculous; two tubercles in the omentum and one on the mesentery.
Lung - -	—	—	2,005	Died, 28 days	General tuberculosis.
			2,006	Died, 26 days	General tuberculosis.
Spleen - -	3	2	2,007	Died, 38 days	General tuberculosis; discrete caseous nodules in the omentum.
Liver - -	—	—	2,008	Died, 29 days	General tuberculosis; the omentum contained about a dozen miliary tubercles.
Muscle - -	—	-	2,003	Killed, 41 days	Caseous nodule in lung; bronchial glands greatly enlarged and partly caseous; spleen enlarged, beset with miliary tubercles; portal gland caseous; no disease of omentum.
			2,004	Died, 26 days	No tuberculosis.
Marrow - -	1	None	—	—	—

PIG 142.

Inoculated subcutaneously under the skin of the ear on April 28, 1906, with 20 mg. of culture from Virus B. V.
Killed May 6, 1906, 8 days after inoculation.

P.M. :—Caseo-necrotic local tumour; the glands at the root of the ear were enlarged and showed on section very early streaks of necrosis. The lungs showed fairly numerous minute grey tubercles, the largest about 0·5 mm. The liver showed under the capsule a few minute grey points. Other organs and glands appeared normal.

Distribution of Bacilli.

Material used.	Cultures.		Guinea-Pigs Inoculated (all Intraperitoneally).		
	Number of Tubes sown.	Number of Colonies observed.	Number of Guinea-Pig.	Duration of Life.	Result.
Blood - -	2	None	2,009	Died 12 days	One grey tubercle in omentum; pyloric gland slightly enlarged; no tubercle bacilli found.
Lung - -	—	—	2,012	Died 20 days	Early general tuberculosis.
			2,013	Died 20 days	General tuberculosis.
Spleen - -	3	13	2,014	Died 31 days	General tuberculosis.
Liver - -	1	Numerous	2,015	Died 12 days	No naked eye evidence of tuberculosis.
Left precrural gland - -	—	—	2,016	Died 41 days	General tuberculosis.
Muscle - -	—	-	2,010	Died 49 days	Omentum normal; small pea-sized caseous nodule in lung; bronchial glands enlarged, firm and partly caseous; tubercles in spleen.
			2,011	Killed 49 days	Two minute grey foci in the omentum; caseous nodule in the lung; bronchial glands enlarged and partly caseous; tubercles in the spleen.
Marrow - -	1	None	—	—	—

PIG 150.

Inoculated subcutaneously under the skin of the ear on April 25, 1906, with 20 mg. of culture from Virus B. V.

Killed, May 9, 1906, 14 days after inoculation.

P.M.—In the subcutaneous tissues of the ear there was a caseo-necrotic tumour with a cavity in the centre communicating externally through a small opening. At the base of the ear near the angle of the jaw there was a large firm gland which on section showed a yellowish or yellowish-white necrotic network in a matrix of grey translucent tissue ; two neighbouring glands, smaller in size, were similarly affected, but in a less advanced stage of necrosis. The lungs were closely beset with grey tubercles, varying a little in size, the largest not quite 1 mm. in diameter ; a good many of the larger tubercles had minute central opacities. The liver substance contained sparsely scattered grey tubercles, the largest 0·5 mm. in diameter ; there was also one tubercle, a little over 1 mm. in diameter, with a yellow centre. The kidneys contained fairly numerous greyish-white tubercles, the largest 1 mm. in diameter. A portal gland showed a few greyish foci. Other organs and glands appeared normal.

REPORT ON THE INFLUENCE OF INDIVIDUAL SUSCEPTIBILITY AND OF DOSE ON THE SEVERITY OF AN EXPERIMENTAL INFECTION BY TUBERCLE BACILLI OF HUMAN ORIGIN.

Dr. L. COBBETT.

REPORT ON THE INFLUENCE ON THE SEVERITY OF AN EXPERIMENTAL INFECTION OF

(1) THE VARIATION IN THE CAPACITY FOR RESISTANCE TO TUBERCULOSIS OF DIFFERENT INDIVIDUAL ANIMALS, AND

(2) THE NUMBER OF TUBERCLE BACILLI INJECTED.

The object of the majority of the injections made here into various kinds of animals has been to ascertain as exactly as possible the comparative virulence of different tubercular viruses. Before exact conclusions could be drawn from these experiments, it was necessary to know what effect upon the result might be caused by differences in (1) the capacity for resistance of different individual animals, and (2) the quantity of tubercle bacilli injected. It also became of importance to know the smallest dose which could be used without these differences in capacity for resistance having a dominating influence upon the result.

(1) The Variation in the Capacity for Resisting Tuberculosis among Individuals of the Same Species of Animal.

(a) *Influence of Age.*

From some of the many experiments carried out at this farm evidence may be gathered confirmatory of the generally received opinion that among the individuals of a given species the capacity for resistance to tuberculosis increases with age. There can, I think, be no doubt that among bovines, calves are distinctly more susceptible than adults. Of this there is plenty of evidence. Moreover, younger calves are more susceptible than older ones. As a rule when two calves were given the same injection they were approximately of the same age and weight. When occasionally this was not so, the younger animal became more rapidly and severely affected. As examples of this one may refer to Calves 113 and 35 [H10.BS], one of which was nearly double as large as the other when injected, and became very much less severely affected with tuberculosis. Also the two calves, 531 and 555, may be compared with the young bull, 611 [H17. Sp. B], Calf 563 with the young bull, 525 [H 7.C.M.], and Calf 387 with Heifer 249 [H10 B.S.] There are no examples of an older animal being more severely affected than a younger one which received the same dose.

(b) *The Influence of Sex. Pregnancy and Lactation.*

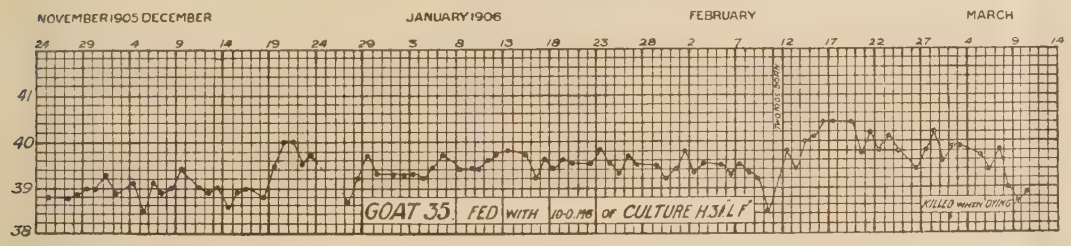
The influence of sex, on the susceptibility to tuberculosis.

Among calves no difference was observed in the capacity of the two sexes to resist tuberculosis.

A goat, No. 35, which was pregnant when fed with a virus of the human Group I, developed a progressing tuberculosis, and was in poor condition at parturition, 79 days after infection. Immediately after this it rapidly became worse, and a month later was killed when death was imminent. The temperature chart of this animal shows clearly the somewhat sudden change which took place after parturition. No cause for this change was observed other than parturition, unless indeed it was some affection of the udder owing to the fact that the kids were dead, and so could not take the milk of their mother. But the udder never became full, so that it was not even necessary to milk it by hand, and nothing whatever was noticed to be wrong with it during life. At the post-mortem examination both it and the uterus were found quite healthy.

The influence of pregnancy and the puerperium.

Chart of Goat 35, *shewing rise of temperature after parturition,*



The course of the disease in this animal supports the common belief that the resistance to tuberculosis is high during pregnancy and suddenly falls to a lower level after parturition. Unfortunately there was no non-pregnant goat infected at the same time with which to compare this animal.

There is little or no evidence confirmatory or otherwise of this belief to be gathered from the heifers which were pregnant when infected with tuberculosis. Of such there were six. In none of these did the condition of the animal undergo any marked change after parturition during the short period that most of them were allowed to live.

It is difficult to say whether pregnancy conferred any additional resistance on these animals, because in only two instances did non-pregnant animals receive identical injections, and so become available for comparison; and in these, unfortunately, the control animals were of a different breed, being Jerseys, while the heifers in calf were Shorthorns. The facts are as follows.

In the Shorthorn Heifer, No. 233, which calved two months after an experimental infection, and was killed four months later, the tuberculosis was minimal, like that in the non-pregnant Jersey Heifer [No. 247], which received an identical injection. It only differed in that in the former animal it had extended to the mammary gland.

In the next pair the tuberculosis was severe, and it was distinctly less acute in the Shorthorn [No. 235], which was in calf, than in the Jersey [No. 243], which was not. This may, of course, be explained on the hypothesis that pregnancy confers some extra capacity for resistance, but on the other hand there is some reason to think the Jersey is racially more susceptible to tuberculosis than the Shorthorn. In evidence of this belief one uncomplicated experiment only can be quoted, namely, that of the Shorthorn Heifer 231 and the Jersey Heifer 237, both injected subcutaneously with a tissue emulsion containing a small dose of the Virus H10. B.S. Neither animal was in calf. The Shorthorn remained well, and developed minimal scattered lesions only, while the Jersey developed severe tuberculosis.

Racial susceptibility; Jerseys and Shorthorns compared.

Thus from the experimental animals here one is not able to gather any sound evidence of the belief that pregnancy is associated with an increased capacity for resistance to tuberculosis. On the other hand, there is no evidence to the contrary.

While one is not able to arrive at any conclusion based on our own experiments as to the influence of pregnancy on the *general* susceptibility to tuberculosis, one can nevertheless point out some rather striking instances which show that those organs which then undergo a sudden increase in functional activity are remarkably liable to become affected during that period.

Susceptibility of organs undergoing a sudden accession of functional activity during pregnancy.

Susceptibility of the Mammary Gland.

The evidence is stronger in the case of the uterus than the mammary gland. Let us take the latter first. I have already mentioned that in Heifers 235 and 247

simultaneously injected with the same material tuberculosis was minimal, and differed in the two animals in that it had affected the mammary gland in the one which was pregnant when inoculated, but not in the other. But since the former lived four months after parturition it is possible that the mammary gland became affected during lactation. Another instance of tuberculosis spreading to the mammary gland in a pregnant heifer occurred in No. 251, in which likewise the tuberculosis elsewhere was minimal. In three other pregnant heifers, Nos. 235, 245, and 259, subcutaneously injected, the tuberculosis did not reach the mammæ. Nor did it reach the uninjected quarters in the pregnant cow, No. 295, which had been injected in the other quarters of the udder. In two of the former the disease elsewhere was severe and steadily progressing. In the others it was minimal.

Tuberculosis of the mamma occurred in a non-pregnant heifer, No. 239, which received a subcutaneous injection of a virus of Group 1. It developed very little tuberculosis elsewhere, but the udder became distinctly enlarged, and yielded a secretion as though it were about to become functionally active, and in this secretion tubercle bacilli were present. It was killed six months after injection, and at the post-mortem examination the gland was found hypertrophied, but there were no tubercles seen in it. Secretion taken from the milk ducts after death caused tuberculosis in guinea pigs which were injected with it.

Tuberculosis of the mammary gland does not commonly occur in calves, or in heifers which have not become pregnant, even among those which develop very acute general tuberculosis. In addition to the above-mentioned animal, it has indeed only occurred here four times, namely, in Heifer 249, and in Calves 477, 575, and 597, all injected subcutaneously. Seven other non-pregnant heifers which received a subcutaneous injection of a virus of Group 1 developed general tuberculosis, but the mammary gland remained normal.

To sum up—among nine heifers which were not pregnant when injected with a virulent virus, tuberculosis of the mammary gland occurred in two, while among five pregnant heifers it occurred twice. In one cow which was pregnant, which received an intramammary injection, tuberculosis did not spread to the non-inoculated quarters of the udder. Therefore the evidence that the mammary gland becomes more susceptible to tuberculosis during pregnancy is not very strong. The evidence that the uterus does so is far clearer.

The following table contains the tests made upon guinea pigs with the milk of [1] the five heifers which calved during an experimental infection produced by a subcutaneous inoculation; and [2] the uninoculated quarters of the udder of Cow 295, which calved after an intramammary injection of the other quarters; and includes also the test made upon guinea pigs with the mammary secretion of Heifer 239, which was not pregnant. The milk of Heifer 249 was not tested.

The Influence of Lactation on the Susceptibility of the Mammary Gland.

There is no complete evidence bearing on the susceptibility of the mammary gland to tuberculosis during *lactation*, owing to the absence of control injections of cows with resting udders.

But the very rapidly fatal tuberculosis which followed the injection of the milk ducts in some of our cows both here and at Walpole might be thought to be in favour of a great susceptibility of this organ when functionally active. On the other hand, when very small doses were used, as in Cow 74 at Walpole, and Cow 295 at Blythwood, the tuberculosis which followed was slow and in the latter case limited; so that on the whole the evidence on this point is inconclusive.

Susceptibility of the Pregnant Uterus.

The non-pregnant uterus has never been found affected with tuberculosis, no matter how severe the disease was elsewhere. The uterus has invariably been found healthy in heifer calves, and was so in the nine yearling heifers injected with viruses of Group 1, which did not become pregnant. On the other hand, three out of six heifers which were pregnant when injected developed tuberculosis of the uterus, and gave birth to tuberculous calves.† This is a remarkably high proportion, and is the more striking because in none of the three cases was the tuberculosis very acute, and in one, while the mammary gland was also affected, there was very little tuberculosis elsewhere.

Two of these heifers, No. 235 and 245, had slowly but steadily progressing severe tuberculosis of the perlsucht type, affecting chiefly the lungs, when killed 176 and 209 days respectively after subcutaneous injection. Another [No. 251] was in good condition when killed 138 days after subcutaneous injection, and nine days after calving. She was found to have a caseous nodule in the mammary gland, and active tuberculosis in the cotyledons of the uterus. The tuberculosis elsewhere was minimal.

Detailed information concerning these animals is given in the following table.

† See Report on congenital tuberculosisat Blythwood Farm, page 261.

TABLE SHOWING THE INFLUENCE OF PREGNANCY UPON TUBERCULOSIS OF UTERUS AND MAMMARY GLAND, GIVING ALL THE HEIFERS WHICH CALVED DURING AN EXPERIMENTAL INFECTION.

No. of mother.	Mode of inoculation.	Virus.	Interval between inoculation of mother and birth of calf.	Interval between birth of calf and death of mother.	Condition of great organs.	Condition of mamma.	Result of milk injections into guinea-pigs.	Condition of uterus.	Result of post-mortem on calf.
Shorthorn heifer 235	S.	H.14. "F.S."	153 days	23 days	Very advanced Perlsucht disease of lungs and pleura. Few tubercles in kidneys and one suprarenal. Minute ulcers in gut, and caseous tubercles in mesenteric glands.	Normal	All four quarters tested 19 days after birth of calf. No tuberculosis.	Early caseation in the cotyledons of the uterine mucous membrane.	Caseous patches and foci in hepatic glands. Emulsions of these glands, of liver, and of a pneumonic lobule in the lung, caused tuberculosis in guinea-pigs.
„ „ 233	S.	H.19. "S.W."	55 days	126 days	Very slight tuberculosis. Several caseous tubercles in thoracic glands and spleen. Three tubercular bodies on lung, loosely attached.	Induration of right hind quarters, in which tubercles are sparsely scattered.	All four quarters tested on several occasions. Guinea-pigs injected from both hind quarters became tubercular, those from fore quarters remained healthy.	Normal	Normal throughout.
Jersey heifer 245 -	S.	H.16. "J.H."	193 days	16 days	Extensive Perlsucht disease of lungs and pleura. Abdominal organs but slightly affected.	Normal	All four quarters tested 6 days after birth of calf. No tuberculosis.	Uterus appeared normal, but tubercle bacilli were found in a cotyledon.	Few foci in hepatic gland, in which tubercle bacilli were found.
„ „ 251 -	S.	H.29. "M.F."	129 days	9 days	Minimal tuberculosis. Small local lesion; calcareous foci in prescapular and thoracic glands. One tubercle in heart.	A caseous mass in left fore quarter. Other quarters appeared normal.	All four quarters tested 3 days after birth of calf. The milk of all the quarters except the left fore infected the guinea-pigs.	The cotyledons were large. From one, when cut, purulent material oozed out. This contained T.B. Besides this, numerous yellow foci were seen in the mucous membrane, in which T.B. were found.	Numerous early caseating foci in hepatic glands. Few early tubercles in lungs, liver, spleen, kidney, thoracic and lumbar glands.
„ „ 259 -	S.	H.10. "B.S."	409 days	4 days	Minimal tuberculosis. Calcareous nodule at seat of inoculation, one in prescapular gland. Two doubtful tubercles in left bronchial gland.	Normal	All four quarters tested on two occasions. Guineapigs remained healthy.	Normal	Normal throughout.
„ cow 295 - -	M.	H.10. "B.S."	178 days	1 day (died)	Small caseous tubercles, and a few larger nodules in the inoculated quarters of the mamma. A few pinhead foci in supra-mammary gland. No tuberculosis elsewhere.	Non - inoculated quarters normal.	All four quarters tested on several occasions. The milk from inoculated quarters only caused tuberculosis.	Normal	Normal throughout.

When one considers these three instances of tuberculosis of the pregnant uterus, giving an incidence of no less than 50 per cent. among the pregnant animals, and contrasts it with the total absence of tuberculosis of that organ among the heifers which were not in calf when injected, many of which were much more severely and acutely affected than these three, one cannot, I think, escape the conclusion that pregnancy greatly increases the susceptibility of the uterus to tuberculosis.

Variation in the capacity for resistance of differential organs.

Before leaving this part of the subject it may be interesting to mention that, quite apart from pregnancy or lactation, the relative susceptibility of the different organs often appeared different in different animals. Thus of the animals which succumbed to acute tuberculosis some died of respiratory trouble; and in them the brunt of the disease was found to have fallen upon the lungs. Others died without dyspnœa being a marked symptom; and in these the lungs still contained a large amount of functional tissue, but the liver and spleen were more affected than in the animals first mentioned. A good example of this difference is afforded by Calves 967 and 969, H10. B.S., which both received 10 milligrammes of the same culture, and both of which had reached a dying condition on the same day, the one with very severe disease of the lungs, the other with plenty of functional lung tissue left, but with more severe disease of other organs than its fellow. Many other instances might be mentioned.

(c) *The Influence of Intercurrent Disease on Susceptibility to Tuberculosis.*

During the course of our work there have been many animals infected with tuberculosis, and some of them have suffered also from other diseases and intercurrent disorders. It is, of course, commonly believed that some diseases, as for example influenza, or even some slight departure from the normal state of health, diminishes the power of resisting tuberculosis. It is therefore of interest to inquire whether these animals infected with intercurrent disease showed any diminished power of resisting tuberculosis. This inquiry is rendered possible because in almost every case of experimental infection of the calf two animals were given identical doses. If then one suffered from an intercurrent disorder, it is possible to compare the course of the tuberculosis in it with that in its fellow. One must, of course, be on one's guard against differences which are due to differences of inherent individual susceptibility, by which I mean differences which are independent of any temporary departure from health. This subject will be dealt with in the next section.

Among the cases of intercurrent disease or disorder which affected one of two animals which received identical injections were many of more or less protracted diarrhœa, sometimes severe enough to cause a marked check to growth, and in one case [Calf 769. H45. F. M.] even to cause death. There were also many cases of more or less extensive carnification of the anterior parts of the lung, caused presumably by an old bronchial obstruction and consequent collapse. In one case there was death from pneumonia [Calf 619. H12. H. N.]. In another the ureters were blocked by gravel and there was acute hydronephrosis of both kidneys. In yet another [Calf 351. H12. H. N.] gravel caused several attacks of renal colic, the nature of which were not at first understood, and ultimately led to blocking of the urethra and extravasation of urine. In one calf an intravenous injection of an emulsion of a softened tubercular tumour from another calf caused both tuberculosis and pyœmia.

Only one of these animals [Calf 877. H28. C. L.] was injected with a virus of the human Group I., which is virulent for bovines. This was the calf which had hydronephrosis from blocking of the ureters. It died a little sooner than its fellow, having general tuberculosis, but death was thought to be due directly to the state of the urinary apparatus.

The other calves, which have been mentioned as having suffered from some intercurrent disease, were all injected with viruses of the human Group II. Even the intercurrent disease did not enable the latter to cause a progressive tuberculosis, nor did it have, as a rule, any obvious effect on the course of the tuberculosis. In Calf 769, which died of diarrhœa 17 days after subcutaneous injection of the virus H45. F. M., tubercle bacilli, it is true, were found widely distributed, but subsequent investigation showed that this was no exception to the general rule. (See the report on the distribution of non-virulent bacilli in the calf. p. 219.) In Calf 955, which had received a subcutaneous injection of 100 milligrammes of culture of Virus H.56. "F. T.", there was found rather extensive carnification of the anterior lobes of both lungs, and atrophy of a considerable portion of one kidney, associated with a deposit of triple phosphate in the corresponding calyces. The animal was never well, and scarcely gained in weight during three months, and yet the tubercular disease had not extended beyond the prescapular lymphatic gland, and was no more severe than in the fellow calf, which had remained well, and grown normally. In Calf 619, which died of pneumonia 83 days after subcutaneous injection of 50 mg. of culture, many little calcareous foci were found, but as these were retrogressive lesions and the pneumonia was recent, they could not be ascribed to its influence, and moreover it seems only reasonable to regard this as one of the more susceptible animals, among which such lesions are not uncommonly produced by viruses of the human Group II. Calf 351 is an interesting instance, because the dose had been enormous (3,140,000,000 bacilli), and in spite of this and the chronic disease of the kidney, the tuberculosis had made no progress beyond the glands nearest the seat of injection. In 409, which had received an intravenous injection, it is possible that the pyœmia may have assisted the tubercle bacilli to multiply in the body, for they were certainly very numerous everywhere—more numerous, I think, than one usually finds after an intravenous injection of a virus of the human Group II.—and had extended to the pyæmic joints.

Many of the rabbits suffered from severe coccidiosis of liver, which sometimes proved fatal; others from an extreme degree of infection with cysticerci, which not infrequently was found to have caused more or less chronic peritonitis and perihepatitis. Neither of these conditions so weakened the resistance of the animal as to enable viruses of the human Group II. to cause a progressive infection, nor did it appear that they had any influence on the severity of an infection produced, either by viruses of this group, or of the virulent Group I.

On the whole it may be said that there is but little evidence to be derived from our experiments here, in favour of the view that the course of tuberculosis is greatly influenced by intercurrent disease, or temporary disorders. On the contrary, it would appear that the resistance to invasion by tubercle bacilli is of a special kind, and not dependent to any great extent upon the *general* state of health of the body.

The evidence of this is, however, far from conclusive. The cases of intercurrent disease in which the virulent viruses of Group I. have been used are too few in number. Really trustworthy negative evidence could only have been obtained from animals injected with virulent viruses in minimal doses. And of such injections there have not been many. And none of them have presented cases of intercurrent disease.

Is a Diseased Part less able to resist Tuberculosis than a Corresponding Healthy Part of the same Animal?

As soon as it became known that after a subcutaneous injection of a virus of the human Group II. into the calf bacilli are distributed all over the body, and that they slowly disappear, it was obvious that one might put to the test of experiment the question whether the tubercle bacilli are more readily destroyed in a healthy than in a diseased part. The most convenient means of doing this was afforded by the frequent instances of carnification of lung. One might inject guinea pigs with approximately equal quantities of emulsion of carnified and normal lung from a calf which had previously been injected subcutaneously with one of the viruses of the human Group II.

This was done in two instances, namely, from Calf 955 and Calf 941. In the former case both the emulsions caused tuberculosis in the guinea pig, that made from the apparently normal part of the organ causing death first. In the latter case the emulsion of apparently normal lung caused tuberculosis, while that made from from the carnified lung killed the guinea-pigs which received it with acute peritonitis ten days later, without any tubercle bacilli being found in the exudation.

Thus the carnified lung does not appear to be more susceptible to tuberculosis than normal lung; but it must be admitted that up to the present the evidence on this point is of little or no value.

Variation in Capacity for resisting Tuberculosis in Normal Individual Animals.

Having dealt with the differences in the capacity for resisting tuberculosis, if any, which are due to differences of age, sex, and condition of general health, as well as with the differences of resistance exhibited by different organs in varying states of functional activity and of health, we now pass on to consider those differences which appear in healthy individuals of the same age, differences which cannot be attributed to any disturbance of general health, nor to any defect in any particular part or organ, which cannot be explained, but which are known as differences in the individual capacity for resistance. For, as we recognise that different species of animals differ in resistance capacity, so also do different individuals, though not to the same extent.

Differences of resisting power of a more or less marked kind among individuals have come to light from time to time among the large numbers of calves and other animals which have been injected in pairs, each individual of a given pair receiving exactly the same dose as the other, and being of the same age and weight. In such cases if there is no intercurrent disease, and the conditions under which the animals are kept are identical, one must attribute any differences in the course and severity of the disease to differences of individual resistance capacity.

I do not propose to dwell on the numerous instances where viruses of the human Group II. were used; for since these any incapable of setting up a progressive tuberculosis in any calf, they do not serve to bring out individual differences of resistance capacity in these animals strongly. Concerning these it is sufficient to recall the fact that many calves developed a few or more little translucent non-progressive tubercles in their lungs or other organs, while their fellows did not, and that the presence of these little bodies was thought to indicate a lower degree of resistance power than the average.

Evidence of Variation in the Capacity of Resistance to Tuberculosis among Calves afforded by Animals Injected with *Tissue Emulsions* of the Human Group I.

Passing on then to the virulent viruses of Group I., we may consider first the evidence afforded by calves injected with *tissue emulsions.*

The following table contains all the instances of two animals receiving precisely similar injections of this kind. The only possible comparison is between the two individuals of the same pair, because different pairs received not only different viruses, but different doses also. All the pairs of animals are given, whether they show any difference in resistance capacity or no, in order that the judgment may be formed of the relative frequency and importance of these departures from the normal power of resistance. In order to facilitate the study of this table, animals which differ markedly in resistance capacity are printed in italics.

TABLE CONTAINING ALL THE PAIRS OF CALVES, EACH MEMBER OF WHICH RECEIVED AN IDENTICAL DOSE OF A VIRULENT EMULSION OF A TUBERCULOUS TISSUE.

† Calf 512 received 30 milligrammes only, Calf 469, 43 milligrammes only, and Calf 1091, 45 milligrammes only, and Calf 887, 23 milligrammes only. Calf 667 which reached the 90 day limit, was in good health when killed, and was found to have general tuberculosis of moderate severity Calf 797 also was killed when in good health and was found to have slight tuberculosis only. All the others died or were in a dying condition when killed & were found to have severe general tuberculosis.

* H.49."T.C." when obtained from man (see calves 957 to 797) was slightly less virulent for Calves than other virulent viruses The other viruses of this group were originally incapable of causing a progressive tuberculosis in calves.

Weller & Graham, Ltd. Litho. London.

The most marked instances of difference in resistance capacity occurred in Calves 153 and 163 [H2, Sp. A]. Calves 159 and 179 [H19, S. W.] and 213 and 223 [H20, F. L.]. The severity of the disease also differed in Calves 35 and 113 [H10, B. S.], but this seemed attributable to difference in age or size.

Nos. 153 and 163 received each 30 c.c. of an emulsion of the tuberculous organs of a guinea-pig. The former was killed when very ill 39 days later, and was found to have severe general tuberculosis. The latter remained well, and when killed 64 days after injection was found to have no lesions beyond the thoracic glands. In the second case Nos. 159 and 179 received each a dose of 10 c.c. of an emulsion of human mesenteric gland not very rich in tubercle bacilli. No. 159 was killed when ill, 50 days after injection, and was found to have severe general tuberculosis. The other was quite well when killed four months after injection, and had only, besides a scar at the seat of injection and a calcareous prescapular gland, a few minute foci scattered in the thoracic, hepatic, and mesenteric glands. In the last mentioned case Calves 213 and 223 each received 10 c.c. of an emulsion poor in bacilli. The former had a moderate amount of disease in the lungs and thoracic glands when killed; the latter only a minimal local lesion and a few calcareous grains in the nearest glands. It must be remembered that these instances represent extreme differences. In them the doses were relatively small. With large doses the results, as a rule, in two calves which received the same dose were very fairly uniform.

Evidence of Variation in the Capacity of Resistance to Tuberculosis among Calves Afforded by Animals Injected with *Cultures* of the Human Group I.

The animals which were injected with culture fall into two groups, namely, those which received 50 mg. and those which received 10 mg. of bacilli subcutaneously. The majority of these animals died of tuberculosis or were killed when they were in a dying condition, the duration of life may therefore be taken as a rough relative measure of the capacity for resistance. In the few cases where the animals were killed when in more or less good general condition three months after injection, this period may be taken as the measure of maximum resistance capacity.

A strict comparison, of course, is only possible between the members of a group all of which received the same dose of the same culture, but since the differences of virulence among the viruses of this group, if they existed, were not marked enough to reveal themselves in our experiments,* H49. T. C. alone excepted, a rough comparison is possible between all the calves which received the same doses.

The evidence as to the existence of variation in capacity for resistance to tuberculosis among these calves is best brought out by the diagrams which appear on p. of this appendix, and in which the duration of life of each calf is shown by a column of proportionate height. If this be consulted it will be seen, among the calves injected with 50 mg. (those injected with H49 T. C. excepted), the duration of life was remarkably uniform, one calf alone living out the period of 90 days*, while all the rest were dying of tuberculosis on an average period of 33·5 days; the shortest being 20 and the longest 63 days.

If one compares together the duration of life of the two individuals of each pair one finds a remarkably close agreement, the widest discrepancy occurring with H10. B. S., where one animal, already mentioned, was killed when in good condition, after three months, and the other when dying on the 34th day.

We may conclude, therefore, that 50 mg. of a culture of the human Group I., when subcutaneously injected, almost invariably produces rapidly fatal tuberculosis in the calf, and is too large a dose to allow individual differences of resistance power to become manifest.

This is not the case when 10 mg. is the dose. Differences of individual resistance capacity are then often great enough to turn the scale from death to recovery. Thus of 41 calves injected with this dose of virulent culture* 30 died, or were killed when dying, in an average period of 44½ days, while 11 were in more or less good condition when killed three months after injection, and in some of these latter the lesions were only of very slight or of moderate extent. Evidence obtained from 10 mg. injections.

Comparing together the duration of life of the two individuals forming each pair, one finds that in eight of the pairs both animals died, or were killed when dying; while in eleven one animal died of general tuberculosis, while the other lived out 90 days, as already stated, and was not very severely affected.

Thus in our experiments with 10 mg. doses the highly resistant individuals were remarkably uniformly distributed among the calves injected with different viruses. This was very fortunate; for it is obvious that if the resistant animals had come together, the results might have been very misleading.

From these considerations it is evident: *That there are considerable differences in individual powers of resistance among different calves;*

That these come more into evidence with 10 *milligramme than with* 50 *milligramme doses;*

That the differences of individual resisting power among calves are such that 10 *milligramme injections cannot be trusted to reveal small differences of virulence among different tubercular viruses.*

(2) THE INFLUENCE OF DOSE.

The influence of the number of tubercle bacilli injected, on the severity of the resulting disease, became apparent at the commencement of our work, and a series of guinea pigs injected by me at Walpole showed that the duration of life after injection bore a very close relation to the quantity of tuberculous material injected, whether this was introduced into the subcutaneous tissue or into the peritoneum. It was not, however, until the results of injecting bovine animals began to accumulate that the full effect of variations of dose became apparent, and it was evident that a tubercular virus which was capable of killing with certainty bovine animals within a few weeks when injected in large doses, would cause only minimal lesions, limited and non-progressive in these animals, if only a small dose were given. It will be sufficient to quote a few instances.

In the case of the culture H. 10 "B.S.," Heifer 249 and Calf 387 were subcutaneously inoculated each with 50 milligrammes of culture, while Heifer 259 and Calf 385 received of the same culture minimal qualities calculated to contain 1,800,000 tubercle bacilli. The two first-mentioned animals developed an acute general tuberculosis, which was rapidly approaching a fatal termination when they were killed 54 and 34 days respectively after injection; the other two, which received the small doses, remained well, and when killed 413 and 202 days later respectively, were found to have only small calcareous nodules at the seat of injection, and a few minute calcareous foci elsewhere.†

The difference of dose was very large in this instance, in the following it was smaller. An emulsion of the prescapular gland of Calf 355 (virus H. 16, "J.H.") was injected subcutaneously in various doses into four calves. The numbers of tubercle bacilli estimated in the qualities of emulsion injected were as follows: Calf 281, 10,900,000; calf 317, 3,000,000; Calf 343, 712,000; and Calf 371, 10,000. In the first three animals acute general tuberculosis resulted, and a fatal termination was approaching when the animals were killed, No. 281 54 days after the injection, and Nos. 317 and 343 in 80 and 68 days respectively. The one which received the smallest dose remained well, and only a few small non-progressive calcareous foci were found in various organs in addition

* The actual culture injected into this animal was probably at fault, for rabbits also injected with it lived much beyond the usual period. That the strain was not attenuated was shown by the injection of calves and rabbits at a later period. These died in the usual time.

* H49 T. C. again excepted.

† For a full description of the post-mortem examinations and other details of the experiments mentioned here, *see* Vol. II. of the Appendix.

to a calcareous local lesion and prescapular gland when the animal was killed 66 days after injection.

In the case of H. 13, "A.D.," three calves were subcutaneously injected with varying quantities of the same emulsion of tubercular tissue from the prescapular gland of Calf 301. The doses were 500 million, 3½ million, and 15 thousand tubercle bacilli respectively. No. 325, which received the largest dose, was killed when dying of general tuberculosis 24 days after injection. No. 321 was killed when very ill 63 days after receiving 3½ million, and was found to have general tuberculosis, while No, 315 which received only 15 thousand, remained well, and when killed 70 days later was found to have no more than a small calcareous lesion at the seat of injection, and very few minute and non-progressive foci elsewhere.

These examples will be sufficient to prove that minute doses do not produce progressive tuberculosis in calves and heifers, even when large doses of the same cause rapidly fatal tuberculosis.

We now pass on to the evidence of the influence of dose which is given by the culture injections. In these the differences were much smaller than in those already mentioned, yet they will be seen nevertheless to have had a marked influence on the result.

In the diagrams already referred to when writing of susceptibility, there are forty-eight calves injected with 50 milligrammes, one with 43, and one with 30 milligrammes, of virulent culture, and forty-three injected with 10 milligrammes of the same. If we exclude the strain H49. "T.C." derived directly from human mesenteric glands, as being probably of slightly lesser virulence than the others, there is, as already stated, no evidence that they differed from each other in virulence, at least they did not do so to an extent which became apparent in the course of these experiments.

In estimating the influence of dose, we may therefore compare the calves injected with 10 milligrammes as a whole with those injected with the larger quantity. The larger dose was fatal to all the forty animals, except one which survived 90 days, while eleven out of the forty-one animals injected with the smaller dose lived three months, and were then in very fair condition. Moreover, with few exceptions, those which died after an injection of 10 milligrammes lived longer than those which received 50 milligrammes of the same culture. The average duration of life of those which succumbed to 50 milligrammes was 33·7 days, while that of those which succumbed to 10 milligrammes was 44·5 days. These differences in the results of injecting 10 and 50 mg. are very clearly shown in the diagrams.

Differences in individual resisting power, however, sometimes had a more powerful result on the severity of the disease than even this difference of dose; and in half the cases where a pair of 10 milligramme calves may be compared with a pair of 50 milligramme calves, the more susceptible of the two former has died in about the same time as the less susceptible of the latter. In one instance the more susceptible 10 milligramme calf died before either of the 50 milligramme animals, while the remaining 10 milligramme calf died at the same time as the remaining 50 milligramme animal.

In rabbits, too, the number of tubercle bacilli injected influences the severity of the disease produced. Rabbits have been injected intraperitoneally with different doses of cultures of all our virulent viruses. These have usually included, 10, 1, 0·1, and 0·01 milligrammes, and the resulting disease, though always fatal, has been the more prolonged, the smaller the dose. This rule has not been without exceptions, differences in individual susceptibility in these animals, as in the calves, not unfrequently overcoming the influence of numbers of bacilli. For the details of the evidence upon which this statement rests, the table of culture injections into rabbits may be consulted.

In one important respect the influence of dose is different in the rabbit and the bovine race. In the latter, injected with a virus of the human Group I., the disease may cease to spread and the animal recover, if the dose be small enough. In the former it appears that there is no dose so small that it will not produce a progressive tuberculosis.

Differences of Pathogenicity between Cultures of Tubercle Bacilli and Emulsions of Tuberculous Tissue.

It will be quite clear from the instances given above that the number of tubercle bacilli injected have a marked influence on the course of the resulting disease when these bacilli happen to be virulent for the class of animal to which the recipient belongs. But there are other factors included in the term dose besides the numbers of tubercle bacilli and their comparative virulence.

In our experience, in order to cause severe tuberculosis with virulent cultures, it is necessary to inject far larger numbers of bacilli than when emulsions of tuberculous tissue are used. In the chapter on the stability of virulence of tubercle bacilli in artificial culture it is estimated that that bacilli injected along with the tuberculous tissue in which they have developed are at least as effective as 100 times as many from an artificial culture of three weeks' growth.

REPORT ON CONGENITAL TUBERCULOSIS AT BLYTHWOOD FARM.

Dr. L. COBBETT.

Many guinea-pigs and rabbits born of tubercular mothers have been killed and examined here, and no case of tuberculosis has been seen by me among them.

Six calves have been born of mothers artificially infected with viruses of the human Group I, and of these three were born tuberculous.

The mothers of those which were healthy at birth had only a very small amount of tuberculosis. Two received very small doses. No. 295 was injected with a quantity of tissue emulsion estimated to contain one million tubercle bacilli into each of two quarters of the udder. She gave birth to a calf 179 days later, and died soon after. The tuberculosis was minimal and limited to the infected quarters of the mamma and to the supra-mammary lymphatic gland. The calf was free from tubercle but died two days after birth. No. 259 received a subcutaneous injection of culture estimated to contain approximately two million bacilli. She calved nearly fourteen months after injection when well and fat, and was killed four days later, and found to have minimal lesions only.

The third normal calf was born of Heifer 233 two months after a subcutaneous injection of a tissue emulsion estimated to contain 53 million tubercle bacilli. The mother was not killed until four months later; besides a small local lesion, she had one or two minute tubercles in the lungs and spleen, and scattered tubercles in one quarter of the mammary gland which was indurated.

The remaining three heifers which calved during an experimental infection, gave birth to tuberculous calves, and each suffered from disease of the uterus. In two there was extensive advanced tuberculosis of lungs of the Perlsucht type. No. 235 received a subcutaneous injection of emulsion containing 4½ million tubercle bacilli: she gave birth to a calf five months later, and was killed three weeks after parturition. The calf reacted well with tuberculin. It was killed twenty-six days after birth. It was found to have caseous patches in the portal lymphatic glands, and a suspicious focus in the lungs. An emulsion of a portion of lung and also one of a portion of the liver which appeared healthy gave rise to tuberculosis after injection into guinea-pigs.

No. 245 received a subcutaneous injection estimated to contain 157 million tubercle bacilli. She gave birth to a calf six months later and was killed sixteen days after parturition. There was extensive disease of the lungs, and but little tuberculosis elsewhere, but a few caseating foci were found in the cotyledons of the uterus. The calf was killed when five days old. A few tubercles were found in its portal lymphatic glands.

The third heifer, No. 251, is even more interesting, because it developed tuberculosis of the uterus and mammary gland, and gave birth to a tuberculous calf, when there was no tuberculosis elsewhere, except at the seat of injection, and a few little retrogressive foci in the nearest prescapular, and in the thoracic glands. The mother received a subcutaneous injection of a tissue emulsion estimated to contain 2,800 million tubercle bacilli; she remained apparently well, and gave birth to a calf four months afterwards. Nine days after parturition she was killed. There was extensive tuberculosis of the cotyledons of the uterus, and a caseous mass in the left fore-quarter of the mammary gland. The calf was killed six days after birth. In its portal lymphatic gland numerous early caseating foci were found; and there were also a few early tubercles in the lungs, liver, spleen, and kidneys, and in the thoracic and lumbar glands.*

The proportion of calves born of tuberculous mothers and affected with congenital tuberculosis is undoubtedly far larger than that which is believed to occur under natural conditions. The numbers are small—three out of six—yet too large to be altogether exceptional. How, then, can this exceptionally large incidence be explained? An experimental tuberculosis is no doubt often a far more acute and rapidly fatal form of the disease than that which usually occurs under natural conditions. Yet this does not explain the high incidence of congenital tuberculosis here, for the mothers in no cases were suffering from the acute form of the disease, and in one, the disease, except in the uterus, was very slight. It will be observed that the proportion of uterine disease was very high, and that congenital tuberculosis did not occur without it. I am inclined to attribute the frequency of uterine disease to the conjunction of two causes: (1) The susceptibility during pregnancy of that organ, as well as of others which undergo a great increase of functional activity, and (2) the distribution of bacilli in large numbers by the blood stream which follows on subcutaneous injection. The last condition probably does not occur under natural conditions, and is, I believe, the dominating reason why congenital tuberculosis has been comparatively so common in the course of our experimental investigations.

LOUIS COBBETT.

* A summary of the particulars of these animals will be found on page 253.

ROYAL COMMISSION ON VIVISECTION.

THIRD REPORT

OF

THE COMMISSIONERS.

Presented to both Houses of Parliament by Command of His Majesty.

LONDON:
PRINTED FOR HIS MAJESTY'S STATIONERY OFFICE,
By WYMAN and SONS, Limited, 109, Fetter Lane, E.C.

And to be purchased, either directly or through any Bookseller, from
WYMAN and SONS, Limited, 109, Fetter Lane, Fleet Street, E.C.; and

ROYAL COMMISSION.

WHITEHALL, 17TH SEPTEMBER 1906.

The KING has been pleased to issue a Commission under His Majesty's Royal Sign Manual to the following effect :—

EDWARD, *R. & I.*

EDWARD THE SEVENTH, by the Grace of God, of the United Kingdom of Great Britain and Ireland and of the British Dominions beyond the Seas King, Defender of the Faith, to

Our right trusty and well-beloved Cousin and Councillor WILLIAM COURT, VISCOUNT SELBY ;

Our right trusty and well-beloved Councillor AMELIUS MARK LOCKWOOD, Commander of Our Royal Victorian Order, Honorary Colonel of the 4th Battalion of the Essex Regiment ; and

Our trusty and well-beloved :—

SIR WILLIAM SELBY CHURCH, Baronet, Knight Commander of Our Most Honourable Order of the Bath, Doctor of Medicine ;

SIR WILLIAM JOB COLLINS, Knight, Doctor of Medicine ;

SIR JOHN MCFADYEAN, Knight ;

MACKENZIE DALZELL CHALMERS, Esquire, Companion of Our Most Honourable Order of the Bath, Companion of Our Most Exalted Order of the Star of India, one of the Under-Secretaries of State to Our Principal Secretary of State for the Home Department ;

ABEL JOHN RAM, Esquire, one of Our Counsel learned in the Law ;

WALTER HOLBROOK GASKELL, Esquire, Doctor of Medicine ;

JAMES TOMKINSON, Esquire ; and

GEORGE WILSON, Esquire, Doctor of Medicine ;

GREETING !

Whereas We have deemed it expedient that a Commission should forthwith issue to inquire into and report upon the practice of subjecting live animals to experiments, whether by vivisection or otherwise ; and also to inquire into the law relating to that practice, and its administration ; and to report whether any, and if so what, changes are desirable ;

Now know ye that We, reposing great trust and confidence in your knowledge and abililty, have authorized and appointed, and do by these Presents authorize and appoint you, the said William Court, Viscount Selby (Chairman) ; Amelius Mark Lockwood ; Sir William Selby Church ; Sir William Job Collins ; Sir John McFadyean ; Mackenzie Dalzell Chalmers ; Abel John Ram ; Walter Holbrook Gaskell ; James Tomkinson ; and George Wilson to be Our Commissioners for the purposes of the said inquiry ;

And for the better effecting the purposes of this Our Commission, We do by these Presents give and grant unto you, or any five or more of you, full power to call before you such persons as you shall judge likely to afford you any information upon the subject of this Our Commission; and also to call for, have access to and examine all such books, documents, registers and records as may afford you the fullest information on the subject, and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

And We do by these Presents authorize and empower you, or any five or more of you, to visit and personally inspect such places as you may deem it expedient so to inspect for the more effectual carrying out of the purposes aforesaid.

And We do by these Presents will and ordain that this, Our Commission, shall continue in full force and virtue, and that you, Our said Commissioners, or any five or more of you, may from time to time proceed in the execution thereof, and of every matter and thing therein contained, although the same be not continued from time to time by adjournment.

And We do further ordain that you, or any five or more of you, have liberty to report your proceedings under this Our Commission from time to time, if you shall judge it expedient so to do.

And Our further will and pleasure is that you do, with as little delay as possible, report to Us under your hands and seals, or under the hands and seals of any five or more of you, your opinion upon the matters herein submitted for your consideration.

And for the purpose of aiding you in your inquiries We hereby appoint Our trusty and well-beloved Charles Clive Bigham, Esquire, Companion of Our Most Distinguished Order of Saint Michael and Saint George, Captain in Our Army, to be Secretary to this Our Commission.

Given at Our Court at *St. James's*, the 17th day of September 1906, in the sixth year of Our Reign.

By His Majesty's Command.

H. J. GLADSTONE.

Note.—His Majesty was subsequently pleased to create Mr. Chalmers a Knight Commander of the Most Honourable Order of the Bath.

ROYAL COMMISSION ON VIVISECTION.

THIRD REPORT.

TO THE KING'S MOST EXCELLENT MAJESTY.

MAY IT PLEASE YOUR MAJESTY,

Availing ourselves of Your Majesty's permission to report our proceedings from time to time, we beg to submit to Your Majesty, as an Appendix to this our Third Report, Minutes of the Evidence taken during the months of April, May, June and July, 1907, as we think the present publication of these documents is desirable.

ALL WHICH WE HUMBLY SUBMIT FOR YOUR MAJESTY'S MOST GRACIOUS CONSIDERATION.

SELBY (*Chairman*).

MINUTES OF EVIDENCE

TAKEN BEFORE THE

ROYAL COMMISSION ON VIVISECTION.

SIXTEENTH DAY.

Wednesday 24th April 1907.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).

Colonel The Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Captain C. BIGHAM, C.M.G. (*Secretary*).

Sir T. LAUDER BRUNTON, M.D., F.R.C.P., F.R.S., called in; and Examined.

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.
24 April 1907.

6777. (*Chairman.*) You are a Doctor of Medicine, and a Fellow of the Royal College of Physicians, a Fellow of the Royal Society, and you have other degrees, honorary and otherwise?—That is so.

6778. I believe you are consulting physician to St. Bartholomew's Hospital?—I am.

6779. And have you taken, from an early period in your studies in medicine, a great interest in this question of experiments on animals?—I have.

6780. And you have had practical experience yourself?—I have.

6781. For a good many years past?—For a good many years.

6782. Did you confine yourself to any particular class of object originally? We have had some witnesses who have confined themselves principally to the operation of drugs, others to particular organs of the body, and so forth. Were your experiments directed to any particular subject originally?—The particular subject at which I was working was to ascertain the action of drugs, especially with a view to utilising them in the treatment of disease.

6783. I think it would be convenient, as some members of the Commission have to leave at a rather early hour, and may not be able to get back soon, if I were to ask you now with reference to an experiment of yours, taking it now a little out of order, that was referred to by Mr. Graham. I think you have had sent to you a note of what he said?—Yes, I have got it before me.*

6784. He quoted from memory, and without reading from the book, some report that he had seen of these experiments, and he gave the general effect of it as being that cats were baked to death in order to ascertain, as I understood, what the effect of a high temperature was on them, or what temperature they could live in. I do not quite understand, from what he said, what the precise object was. Perhaps you will explain the experiment in your own way?—Yes; and perhaps I might be allowed to go back a little further even than that experiment, because, by doing so, I should give a sort of continuous view of what I was doing.

6785. If you please?—In 1870, Professor Stricker found that rabbits, when completely narcotised with chloral, lost their power of maintaining their temperature and died. If those same rabbits, instead of being laid out upon a table, where they could cool readily, were simply enveloped in cotton wool, they lay senseless for many hours and ultimately recovered.

6786. You mean enveloped in cotton wool during the experiment?—Practically what he wanted to do was to examine the tissues microscopically, their ears, and so on, and he found it was convenient to render them completely senseless and immobile by a large dose of chloral, that rendered them completely senseless so that they could neither feel nor move. They remained in this condition for many hours, but unless they were kept warm they ultimately died. If, however, he simply wrapped them up in a sheet of cotton wool, at the end of several hours they began gradually to recover. He directed my attention to this, and I found that if, instead of merely wrapping them up in cotton wool, I kept them warm artificially with an ordinary hot water bag, or by a tin hot water can, the animals would bear a bigger dose of chloral, and still recover, than if they were simply wrapped up in cotton wool. And I am glad to say these experiments of mine have borne practical fruit; because, not very long after I published them, the late Dr. Young, of Florence, had a case of an overdose of chloral, when the patient, an old lady, would certainly have died but for the fact that he remembered the results of my experiments, about which I had been conversing with him. He wrapped her up in cotton wool and put hot water bags round her, and she came round. That was the first thing that drew my attention to the effect of temperature upon the action of drugs. The next thing I wanted to find out was why certain drugs, given in cases of disease accom-

* *See Questions* 5844–5849, 6079–6081, 6131–6140.
Dr. Graham, in returning his own corrected evidence on 15th March, had also appended the following note:—"Though there is nothing to correct in the above account, it may save time and controversy if I add that since I gave evidence I have looked up the detailed account of the experiments which preceded the above and which were recorded in the Reports of St. Bartholomew's Hospital for 1871, *Vol. VII., p.* 216, *by Sir (then Dr.) Lauder Brunton alone. He gives details of his method. The animals were narcotised only with chloral—once with laudanum—and so were kept still. The heating apparatus was a tin with double bottom and sides into which hot water was poured, and a hot water bag was put on the belly. The heart was pierced by a needle and the thermometer was in the rectum. These methods may or may not have been followed in the later series I quoted.* J. W. G.

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

panied by high fever, do not act in the usual way. It was pointed out by Professor Thomas that pneumonia, when treated by digitalis, does not yield to digitalis in the way you would expect from the action of the drug upon a healthy man. The digitalis seems, in the case of a person having pneumonia, not to act upon the heart in the same way that it would upon an ordinary person. It occurred to me that this might be due to the effect of temperature upon the heart, and so I proceeded to make a number of experiments upon animals with high temperatures. If you keep a healthy animal or a healthy man in a warm place, as a rule their temperature does not rise very high; it rises a little, but not very high, as everyone knows who has gone into a Turkish bath; but if you narcotise an animal completely, and then keep it warm, it has lost its power of regulating the temperature, and the temperature goes on rising and rising until the animal dies, although the animal remains perfectly unconscious for the whole time. I therefore narcotised animals (and especially I used rabbits in that series of experiments) by a large dose either of chloral or opium. I then placed them in a bath, of which I have had a copy made. The object of the experiment was to imitate the conditions of a patient suffering from high fever and lying in bed. To have had any pain inflicted would have tended to vitiate the experiment. The description was fully given in the paper that I wrote in the St. Bartholomew's Reports, Volume VII, for 1871, at page 218.

6787. Will you please read the description of the bath?—"These experiments were made by narcotising the animal with opium or chloral, and laying it in a tin vessel about 20 inches long, by six inches broad and three inches deep in the inside, and well padded with cotton wool. The vessel was double, and by pouring hot water into it the temperature of the rabbit was gradually raised. The belly of the animal was also covered with cotton wool, and sometimes with an india rubber bag containing hot water. To make respiration easier a cannula was introduced into the trachea, and in some experiments the inspired air was passed over warm water so as to warm it and saturate it with moisture, and lessen the loss of heat from the lungs."

6788. I thought it necessary to ask for that description, because Mr. Graham said that the animal, a cat, I think he said, was put into a stove and baked to death?—Yes, and Miss Frances Power Cobbe also described these experiments as "roasting to death."

6789. (*Sir William Church.*) Mr. Graham's words are: "They were put into a kind of stove and were heated until they died"?—Yes. Then I may pass over the means, perhaps, of recording the beats of the heart; and then I go on to say: "As the animals were completely narcotised and remained perfectly motionless, the thermometer remained undisplaced in the rectum from the beginning to the end of the experiments." That shows how complete the narcosis was, that the thermometer introduced into the rectum remained perfectly undisturbed the whole time. The animal did not make the slightest movement.

6790. (*Chairman.*) Are we to understand that the object of this experiment was to test to what temperature you might safely raise the heat of an animal while it was under narcotics?—No; the object of the experiment was to find out what the condition of the heart was in what is known as hyperpyrexia. In many cases of disease the temperature of the patient rises high above the normal, and then these patients are in a state of extreme danger, and unless you can reduce the temperature in some way we know that these patients will die. The object of these experiments was to find out what the condition of the heart and circulation was in pyrexia, and especially in hyperpyrexia, so that one might be able to use appropriate remedies to reduce the temperature and slow the circulation.

6791. Was the animal operated on after it was in this box or while it was in the box?—There was almost no operation done on it. The only operation that was done was that it was first of all completely narcotised by a subcutaneous injection of chloral or opium; the animal became completely senseless, and then a cannula was introduced into the trachea at the same time to allow us to warm the air entering the lungs. The only other operation done upon it was to put an ordinary sewing needle between the ribs and attach it by means of a thread to a lever so as to record the movements of the heart, in order to see how quickly the heart was beating in accordance with every rise of temperature in the animal. The object was to ascertain the action of the high temperature of the hyperpyrexia of the high fever upon the organs of the body, and especially the heart, with a view to finding out how we were to prevent danger of death to our patients when suffering from high fever.

6792. And did you attain the object?—To a certain extent, yes.

6793. Do you consider that the experiment was a useful one?—Certainly.

6794. Not only justifiable to try it, but it was useful in its results?—Assuredly, I think.

6795. (*Sir Mackenzie Chalmers.*) The experiment was absolutely painless throughout?—Absolutely.

6796. (*Chairman.*) I think, in fact, if I recollect aright, Mr. Graham said in his evidence that obviously it was impossible to perform it under anæsthetics?—Yes, he said so. This is not the series of experiments referred to by Mr. Graham, but this is the apparatus used in the series, to which he refers in "The Practitioner."

6797. Before you finish with that, was the rabbit killed before it came out of the anæsthesia, or was it allowed to recover?—They were all killed, either killed or died from the effects of the chloral.

6798. (*Mr. Tomkinson.*) I thought the object was to see whether they would not recover by the preservation of their heat?—No, excuse me; these are two entirely different series. The first series of experiments I referred to was upon the effect of heat in preserving life; this second series was upon the effect of heat in causing alteration in the heart.

6799. (*Sir William Church.*) As a matter of fact, these animals were narcotised by a poisonous dose of chloral or morphia?—Always.

6800. So that they naturally died?—Yes, these animals would have died anyhow whatever we had done to them.

6801. We have been told here repeatedly that morphia is not an anæsthetic; that depends, of course, upon the quantity. We have been told also that chloral is not an anæsthetic; that also depends upon the quantity. These animals receive poisonous dises in order to completely narcotise them?—Yes; and as to the statements that chloral and opium or morphin are not narcotics, and do not remove pain, there is no other word for it, it is simply a lie; you may as well say that chloroform does not remove pain. If you give any animal a sufficiently large dose of chloral or opium, you so completely abolish sensibility that there is nothing you can do that will awaken its sensibility; you might burn it alive, you might throw it on the coals, and it would remain unmoved. I have never tried it, but I know you can conduct any experiment which would in the ordinary nature of things be painful, but there is no pain attached to it. The animal is as senseless as a piece of board.

6802. (*Colonel Lockwood.*) But it all depends on that statement "if a sufficiently large dose is given"?—Quite.

6803. (*Chairman.*) You are speaking of chloral and morphia?—I am speaking of chloral and morphia. I may say that nearly all my experiments were done after I had been in Professor Ludwig's laboratory in Leipsic, in which the invariable rule was that before any experiment was done the animal should be thoroughly narcotised. Dogs were frequently used, and the way they narcotised them was to inject into the vein that runs on the hough joint, and which is there prominent, at least a drachm of tincture of opium. The usual effect of this was that in less than half a minute the animal was completely senseless, and never came round.

6804. You were going on to the actual experiment which Mr. Graham was referring to in his evidence. What you have told us was introductory, leading up to the other?—Yes; he refers to the "Practitioner," Volume 33, page 273; and the reason why I have given this long explanation of this series of experiments is not only that Miss Frances Power Cobbe described this series as "roasting rabbits alive," but that the second series, the series with digitalis referred to by Mr. Graham, were a continuation more or less of this first series, and were made in exactly the same way. At page 275 of the "Practitioner," Volume 25, the papers quoted by Mr. Graham—Dr. Cash and I say, after referring to the first series of experiments, which I have

just been describing, "In experiments of the same kind which we have made upon cats"; and the reason why no full description of the method of the experiment was given in the "Practitioner" was that the whole method had been so completely described before that anyone who wished to know how the experiments were conducted had only to refer to the former paper.

6805. When you say, "In experiments of the same kind," what was the preceding sentence; because I suppose it referred to the previous experiments?—Shall I read the whole?

6806. What I want to get at is this: I want to see whether a person reading those words, "of the same kind," would have any means on that page of tracing back and seeing what the previous experiments were; because it is assumed that these animals were slowly baked to death without any anæsthetics, as Mr. Graham says?—Then, perhaps, I had better read the sentence before: "We have therefore attempted, as a first step in our investigation, to ascertain the effect of rise of temperature alone on the pulse in the cat, which animal we employed in the present research. In a former series of experiments made by one of us——" Then comes, in a footnote, a reference to this series, to which I have already referred, "on the effect of heat upon the pulse in the rabbit, it was found that the pulse-rate increased with considerable regularity as the temperature of the body rose, as is shown by the following experiments, in one of which the vagi were uncut and in others were cut. At the commencement of the experiment there were slight irregularities before, which have not been copied here. After the temperature had risen above a point which is marked by thick type in the table, the pulse rate began to fall." Then follows a table of the temperatures and the corresponding rates of the pulse; and immediately after the table comes the expression I have just used: "In experiments of the same kind which we have made upon cats."

6807. So that any investigator reading that and seeking to ascertain the whole truth about it, would have the means of seeing precisely what the nature of the experiment was?—Precisely.

6808. And the conditions under which it was performed?—Precisely—the reference is fully given; and the reason why it was thought unnecessary to give it again was that anyone who wished to ascertain precisely how the experiments were done could do so by referring to the original paper—the first paper. But this paper on digitalis was not written for physiologists or pharmacologists, but for general practitioners, and had a practical object in view; it was to tell them what alterations they might expect to find in the action of digitalis if they gave it to a person suffering from high fever; and so after giving, in such a way as the general practitioner would understand, a *résumé* of our results, we then went on to the practical conclusions, which are practically that "The administration of digitalis, or of drugs which act like it, to patients in a febrile condition is therefore likely to have much less effect upon the pulse than at the normal temperature; and if the temperature be very high they may have no effect at all whilst this persists." And then comes rather an important point: "When the temperature began to fall the pulse naturally became slower, and this slowness is increased if digitalis has been given at the height of the fever. It is therefore evident that digitalis and its congeners, if they are given at all when the temperature is high, should be given with great care; for, otherwise, the medical man may be induced, by the apparent inaction of the remedy, to push its administration too far during the fever, with the consequence of producing too great depression of the pulse during defervescence." Now this is a very great practical danger, because, in a case of high fever, you are tempted to use every means in your power, and to push every means to reduce the temperature, and to slow the pulse, which is going tremendously quickly; and you are apt to forget that in a fever like pneumonia, which ends after a definite period, the temperature will fall and there will come a condition of defervescence, and very likely of collapse, and that if you are careless in pushing your digitalis too far during the fever you may help to produce a greater condition of collapse after the fever is over and kill the very patient you want to save.

6809. Was this experiment that you made with a cat conducive to, or was it essential to, the discovery of which you have just told us?—Yes, surely. I do not see how you could have done it without.

6810. You say it was necessary; it was the way in which it was discovered?—It was the way in which it was discovered, and I do not see how you could have discovered it in any other way. The only other way in which you could do it would be to experiment upon a number of patients. The difficulty in experimenting upon patients is that every medical man who is called in to a patient feels himself bound to do his best for that individual patient. He is not called in to advance the science of medicine by what he tries upon his patient; he has got to consider that individual patient and do the best for him. Whereas, if you are working upon a lot of animals, you do what is best to attain knowledge without considering whether the animal is going to reap any particular benefit from what you give it or not.

6811. I think every member of the Commission would agree with you there, that when a doctor is called in his first duty is to his patient and not to science?—Surely.

6812. That is your description as given from your book and your comment of actual experiment which is referred to here?—Yes, and here I have had a model made.

6813. I should like to have this quite clear, without referring back again, that the heating was carried on in the way which you have described in that box with cotton wool and under a fatal dose of chloral?—Yes, or of morphin or of opium.

6814. Ultimately fatal?—Yes.

6815. Then I gather that it is not true to say what Mr. Graham says in answer to this question: "You do not wish us to understand that these poor creatures were slowly baked to death, because that could not be under anæsthesia, and it would be most awful torture"? To which he replied: "They were slowly done to death by heat." That, taken in conjunction with the question, is not very accurate?—It is not so.

6816. (*Colonel Lockwood.*) Do you say chloral and opium?—No, chloral or opium. Once or twice I have used the two together, but as a rule it is unnecessary to use the two; but once specially I remember using the two together.

6817. (*Sir William Church.*) But as a matter of fact in your second series of experiments on these cats the majority of them did not recover, I think?—No, those all died too; they all got this fatal dose. But then there is yet another series which, perhaps, I had best refer to, they have not been referred to in the evidence, but still Mr. Graham has evidently got a notion of a stove of some kind.

6818. I think, if I might say so, Mr. Graham mixed up the sets; because he led me to think that some of the animals recovered?—He has probably mixed up yet a third set, and these were a series of experiments upon the action of aconite as an antipyretic. In many cases of fever small doses of aconite seem to reduce the fever very much; and so Dr. Cash and I tried to see how far the aconite would do this in animals, and more especially we used pigeons. In pigeons the temperature is higher than in ordinary animals; the normal temperature of a pigeon being about 104, whereas in man it is only 98.2 Fahrenheit. With these pigeons we did use a kind of a box, and as that will very likely be referred to later on—I mean that they may mix it up again—I have thought well to take the box question up as well. This box was simply a metal box with a glass top, and surrounding the metal box was a second case in which you could put either hot or cold water, so as to raise the temperature of the box to such a degree as we liked. We padded the inside with brown paper, so as to prevent any contact of the animal with the metal itself, because we did not want any local chill or any local burning to vitiate the experiment. All we wanted to do was to find out the condition of fever such as would occur in a patient in bed. We raised the temperature of the animals by raising the temperature of the box, in some cases to 106 Fahrenheit; but this can hardly be described as baking alive, because I have found by inquiry at the Jermyn Street Bath that, whereas our highest temperature was 106 Fahrenheit the lowest temperature of the Jermyn Street Bath is 120 Fahrenheit, their highest temperature running up to 230.

6819. (*Chairman.*) Do you mean the temperature of the atmosphere at which the animal was was 106?—Yes. May I bring the figure of the box round to show it you? (*Exhibiting the figure of the box to the Commissioners.*) We raised the temperature of the box in some cases up to 106°.

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

6820. (*Mr. Tomkinson.*) That was the temperature of the air which the animal breathed in the box?—Yes.

6821. 106° only?—Yes, whereas the lowest temperature of the Jermyn Street Baths is 120°.

6822. The first room is 120° or 125° and runs up to 220°?—Yes.

6823. I have sat in 200° myself?—So that although a box was used here which might be described as a stove, an animal was put into it, the pigeons sometimes at 107° did show symptoms of discomfort and feeling too hot; but that could hardly be described as roasting them alive.

6824. (*Chairman.*) Mr. Graham refers to the temperature of the cat, he says, as being raised to 111° in one case and 113° in another. Was it in that experiment?—No; that was in the series of experiments of which I spoke before.

6825. The rabbit?—No; that was the one with cats on digitalis, but carried on with the same instrument as the experiment on rabbits.

6826. Carried on in the tin bath?—Yes; the tin bath I have already shown, and of which I have read the description (6787). If you narcotise a cat completely with either chloral or with opium and leave it just with the cotton wool round it, and it is warm, its temperature gradually rises, because the narcosis disturbs the normal power of regulating the temperature, so that the temperature of the cat will rise to 111, 112, and 113, and then that is hyperpyrexia, and they die, just as those patients who have acute rheumatism often die with high temperature in a hospital ward.

6827. In the case of the cat, the intention was that it should not recover?—That it should not recover.

6828. And you were testing it under this complete anæsthesia to see at what point that hyperpyrexia would occur?—Yes, that was, however, rather incidental. What we wanted to find out was the condition of the heart throughout.

6829. I should rather say that you were testing it with the full understanding that it would occur at one point?—Yes.

6830. (*Colonel Lockwood.*) I only wish to ask you a few questions as to the present law. I note that you say in your *précis* that the law, instead of being made more stringent, ought to be relaxed. Do you look upon the present laws on the subject of animal vivisection as a stop to science?—To a certain extent I do.

6831. And in consequence, do you think that our knowledge of science is behind that of foreign nations where those laws do not exist?—It would be behind if the foreign nations had the same laws as we have; but we keep pace with them by learning what they are doing. We depend for a great deal of our information upon what we get from abroad.

6832. Then our superior intellect enables us to outstrip them?—In some cases; certainly not in all.

6833. Therefore I presume you would be very much opposed to any further restrictions upon experiments upon living animals?—Surely. Perhaps I might be allowed to give one illustration of how the Act has interfered with work which might have been beneficial. About 1871, with Sir Joseph Fayrer, in making experiments upon snake venom, we found out that there were certain substances which would destroy snake venom absolutely; but we had not succeeded in obtaining immunity or saving life after a big dose had been injected. We could not administer the antidote in such a way as to prevent the action of the poison when once introduced. Then came the anti-vivisection laws, and we could not continue our experiments at all at home. The consequence of that was that they lapsed for a number of years, and they were only taken up again about two years ago by Major Rogers. He was able to take them up again because Professor Waller had invented a method of giving chloroform continuously for thirty hours or more, so that he was able to give the poison and then keep the animal for many hours under the anæsthetic, and then he could try the effect of the antidote. I had invented a small lancet which I thought might be useful, but it had not practically been tried until Major Rogers got this chance of doing it, when he found that it answered quite well. He has since been using it in India, and has, I think, now got either seventeen or twenty cases of snake-bite in which the persons would almost assuredly have died and who have been saved by the use of the instrument. I have one here; it is made in two forms (*exhibiting the same*). It consists of a small lancet, in the handle of which is some permanganate of potash. In using that, the punctured wound made by the snake's fang is simply converted into a slit, and permanganate of potash is rubbed in after being wetted with saliva.

6834. You claim that your little lancet has been discovered by the assistance of experiments on living animals?—It was made in consequence of a number of experiments that I made with Sir Joseph Fayrer.

6835. (*Chairman.*) Colonel Lockwood's question was whether the shape of the lancet was discovered by experiment. I do not know whether you mean that?—The shape of the lancet is of no importance.

6836. (*Colonel Lockwood.*) I did not mean that.

6837. (*Chairman.*) The cure is by permanganate of potash?—Yes.

6838. (*Colonel Lockwood.*) All obtained by experiments on living animals?—Yes, experiments which were made quite thirty years ago.

6839. Have you ever used curare only, in experiments on living animals?—Yes.

6840. Latterly?—No, I cannot very well say whether I have used it only.

6841. When performing an operation under licence from the Home Office?—No, any experiments I made with curare would be previously to the existing law.

6842. (*Chairman.*) Previously to 1876?—Yes.

6843. (*Colonel Lockwood.*) And never since?—I cannot say that I even did it before. It is just possible that I may have done it, but I cannot recollect it.

6844. Have you witnessed a very great number of experiments, and conducted yourself very many?—Yes.

6845. Do you, or do you not think that further inspection of laboratories where these experiments are carried on is advisable?—I do not think it would be any good at all; I do not think it is advisable.

6846. You believe that the experiments in these laboratories are conducted absolutely painlessly?—Yes.

6847. And without unnecessary suffering?—I do.

6848. (*Sir William Collins.*) In the interesting *précis* which you have sent us I see you state that in your opinion the majority of those who desire the abolition of experiments on animals" are actuated by praiseworthy motives"?—Yes.

6849. But you think that their opposition is founded on ignorance?—In many cases it is, I am sure.

6850. You trust that the evidence taken by this Commission may help to dispel that ignorance?—Yes.

6851. I see you call attention to the importance of bearing in mind a liberal interpretation of the word "experiment" in dealing with the whole question of the effect of experiments upon living animals for scientific purposes?—Yes.

6852. You speak of experimentation as the condition under which all living beings exist?—Yes.

6853. And you say that medical men also know only too well that every effort they make to alleviate pain or cure disease is an experiment made on their patients?—Yes.

6854. Then you refer to the natural experiments, as it were, of epidemic diseases, as in the case of the epidemic of measles in the Fiji Islands?—Yes.

6855. You state in regard to that case that a disease which like measles is comparatively harmless in a population where it is endemic, as in this country, may become a devastating pestilence when introduced into a country like the Fiji Islands, where it was formerly unknown?—Yes.

6856. Do you mean that it was because of the action on a virgin soil, as it were, that the fatality was so great in that case?—I think that was so; I believe that you actually do get people used to the conditions under which they are, both hereditarily and personally. Newcomers, when going to Venice, for example, suffer from diarrhœa and disorders of the digestion, which people who are living in Venice do not suffer from, although they are under exactly the same conditions, drinking the same water, smelling the same smells, and altogether under the same conditions.

6857. With regard to that particular epidemic of measles in the Fiji Islands in 1874, do you happen to remember the remarks upon it of Hirsch, in his "Historical and Geographical Pathology"?—I do not.

6858. I see that under the head of "Severity of type due to neglect of the sick," he suggests that the mortality in that case was due to the fact that the afflicted were exposed unattended and untreated. That consideration would have to be borne in mind in assessing the cause of fatality there, would it not?—It would; but, of course, in the Fiji Islands, leaving them unattended would not have the same bad effects as it would here. The climate of Fiji has to be taken into account as well.

6959. I see Hirsch suggests that every complication was invited and rendered more intense by this neglect and exposure?—I should think it is very doubtful indeed. I do not think Hirsch ever went to the Fiji Islands. I have never been there either; but I have known people who have been there, and from what I learn about the climate there, it seems to me that Hirsch's remark is perhaps not to be taken too literally.

6860. Do you know also that he suggested that those that were treated did not die at an unusual mortality in that particular epidemic?—No, I did not know that.

6861. With regard to snake poison, I see in the little box you have handed into the Commission there is a paper which states "The best remedy that can be carried out for this purpose" (that is to say, against snake-bite) "is permanganate of potash, the efficacy of which as an antidote to the poison, not only of the cobra, but of other venomous snakes, when properly applied, has been conclusively demonstrated"?—Yes.

6862. Do you agree with that?—It might be advisable for this Commission to get Major Rogers to tell them exactly what he has found. He has, I think, seventeen or twenty cases, or perhaps more, which have been quite successful.

6863. When did Major Rogers begin the experiments to which you allude. What is he?—He is in the Indian Medical service, but he is home just now on leave.

6864. Will you tell the Commission when he began the experiments; you said a short time ago; you did not mention the year?—I think it was about three years ago. It was 1904.

6865. (*Chairman.*) There have been experiments, I understand, upon animals to test the nature of permanganate of potash?—Yes, there were experiments made by Sir Joseph Fayrer and myself about 30 years ago. Those were stopped in the middle because of the vivisection laws, and they were taken up again, in 1904, I find it is, by Captain Rogers, as he then was, and he was able to continue them because he had got an apparatus for keeping an animal under an anæsthetic for thirty hours, so that he could give the snake poison and give the antidote and see whether the animal lived.

6866. (*Sir William Collins.*) Are you acquainted with the experiment of Calmette and others with regard to anti-snake venom sera?—Yes, perfectly.

6867. Do you agree that a serum has been found which is valuable against snake bite?—Certainly. But the difficulty is that the serum that is prepared, for example, for a krait, will not act for a cobra, and *vice versa*, whereas this will act for any poisonous snake, for krait, cobra, or water snake.

6868. Then permanganate of potash in your opinion is a universal remedy?—Yes, and more than that, I can testify from my own experience that it is an antidote to ordinary septic poisoning.

6869. And you regard that as conclusively demonstrated?—Yes.

6870. Have the various treatments by serum and your treatment been largely utilised in India?—Not yet. The difficulty of the serum treatment, of course, is that the serum and the snake are not likely to be in the same place. You do not always get the snake and the serum together as in Calmette's case, where he got bitten while lecturing, and applied the serum forthwith, which he made himself. As a rule you cannot use the serum, and even this lancet has not been largely used yet. It is only just beginning to find its way; but I think that already Major Rogers has had 17 or 20 successful cases.

6871. You can hardly say that the mortality from snake bite in India has as yet been reduced by any treatment based upon experiments on animals, can you?—One can say definitely that it has been reduced; it has been reduced; it has been reduced at least by 17 or 20 cases. But we cannot say in what proportion it has been reduced. I do not know how many people have tried this lancet, but in 17 or 20 cases where it was tried it was successful, and in so far the mortality has been reduced.

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

6872. I see in the year 1905 according to the official figures, there were 21,797 deaths from snake bite in India?—Yes.

6873. A mortality of 94 per million living?—Yes.

6874. Whereas in 1876 there were 15,819 deaths, or a rate of 85.4 per million living?—Yes.

6875. So that apparently the numbers at present are unfortunately increasing?—There is all the more need for a liberal distribution of these little lancets.

6876. Has the Indian Government adopted them?—I do not think it has. If it would simply adopt these little lancets and sell them, as it sells packets of quinine for a few pice at every postage station, the mortality in India from snake bite would be very materially reduced in a short time.

6877. Or distribute them gratuitously?—If they would sell them at cost price, they might be produced on a large scale at about a half-penny each, I believe. Of course the Indian peon is an awfully poor man. The price of a lancet represents so much rice to him.

6878. But if you wish to let your antidote be as universal as the bane, it would be desirable to make it gratuitous?—Yes, it would be.

6879. Can you refer me to a record of the 17 or 20 cases in which the success has been conclusively demonstrated?—I am not sure that I can, because I chiefly quote from a letter to myself from Major Rogers; but he has, I know, published some of them.

6880. Can you refer me to the publication?—No, but I will get it for you willingly.

6881. Is Major Rogers a Government official?—Yes, he is Professor of Pathology in the Calcutta Medical College.

6882. Would the report on these 17 or 20 cases in which the efficacy of the remedy has been conclusively demonstrated, appear in an official report?—I do not know whether it is an official report or whether it is in a medical journal, but it will be in one or the other no doubt.

6883. Have you the letter by you on which you base your evidence?—No, not here, but I have got it by me. If you would like the letter I can send it on.

6884. (*Chairman.*) Major Rogers himself is in England, you say?—Yes, I can send you his address. He is, I think, working every day at the School of Tropical Medicine, and he gave the lecture on kalaazar before the Royal College of Physicians two or three weeks ago.

6885. And if the letter is not a private one perhaps you would let us have a copy of it?—Certainly.

6886. (*Sir William Collins.*) As to the administration of digitalis in pneumonia, I asked the President of the Royal College of Physicians, Sir Douglas Powell, when he was here, whether he would give us his opinion as to any rules which have been obtained as the result of experiments on living animals for the administration of digitalis in pneumonia, and he replied that he was not aware of any experiments which had established the usefulness of digitalis specially in pneumonia?—That is quite true. The usefulness of our experiments was chiefly cautionary. That a man might be tempted to use digitalis in pneumonia and thereby do harm.

6887. Is it the result, in your opinion, that digitalis ought not to be used in pneumonia?—My own belief is that sometimes it may be useful, but as a general thing it is advisable not to use it. Our experiments showed that it is possible to use digitalis in pneumonia and thereby do harm.

6888. Then in regard to amyl nitrite, a question which has been raised by other witnesses, I see that in your *précis* you state that by finding in a case of angina pectoris that the blood pressure rose too high, and having learned through experiments on animals that nitrite of amyl would lower the pressure, you applied

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

the drug to the treatment of the disease with perfect success?—Yes.

6889. What was the date of the first publication of yours on the subject?—It was in July, 1867.

6890. In that publication did you refer to a previous work of Sir Benjamin Ward Richardson upon the subject?—Yes.

6891. Did you say "Little attention, however, was paid to it for some years until it was again taken up by Dr. B. W. Richardson"?—Yes.

6892. Have you seen Dr. Richardson's statement in regard to it in his book called "Vita Medica"?—No, I do not think I know it. I only know his published papers in the British Association reports.

6893. It has been doubted whether the discovery of nitrite or amyl was based upon experiments upon animals or trying it on the human subject. Dr. Richardson stated, "Research with nitrite of amyl proceeded in the usual way. I made myself the first victim, and tried the effects of the substance by taking it both in the form of vapour and fluid. I had also some friends who were willing to follow in my wake." Did he not produce it at the meeting of the British Association, I think in 1863, when its effects were noted by some of those present, who tried it by inhalation?—It may have been so; but his chief account of nitrite of amyl is given in the Report of the British Association for 1864, where he refers to an earlier paper which he had read at the Newcastle meeting in 1863; but on looking up the volume for 1863 I cannot find any reference whatever to Dr. Richardson's paper, either in the Index of the Report or in the Index of Communications. I have brought it here so that there should be no mistake. This is the volume for 1863 (*handing in the same.*) So that it cannot have been of any very great importance, I think. Then in the Reports for 1864 there is a very full account, but his reports deal much more, in 1864, with the experiments upon animals than the experiments upon himself. Here are the experiments upon animals (*handing in the volume*). He gives here those upon the skin and so on. Then at page 126 he gives a *résumé* of its action. Then in the next year he took it up again, in 1865, at Birmingham, and he again gave a *résumé* of its action even shorter than what he gave in 1864. Perhaps I might read the *résumé* that he gave himself. He says, "Before proceeding further, permit me to invite the attention of the section to a very brief summary of the facts brought forward at our last meeting in 1864, respecting the nitrite of amyl. I showed then that nitrite of amyl was: 1. The most powerful excitant of vascular action known. 2. That in animals whose bodies admit of its spontaneous evaporation, the nitrite suspends animation, and that in animals of higher organisation it induces a condition resembling cataleptic insensibility. 3. That it is not an anæsthetic. 4. That the effects produced by it are developed on the motive powers of the organism, which it first vehemently attacks, and then paralyses. 5. That it arrests the process of oxidation." So that, you see, all he did there was to show that it was a "powerful excitant of the vascular action," without going into details. He did suspect, and correctly, that the excitement of the heart was probably due to the effect of nitrite of amyl in dilating the capillaries and lessening the resistance; but he did not pursue that any further. He went on, in his report of 1865 and later, to discuss the question of the action of other compounds of amyl, and left the nitrite, which was the most important, alone; so that the question of how it acted remained unsolved. It was then taken up by Rutherford and Gamgee, who made experiments upon animals with an ordinary manometer, and found that the blood pressure was greatly reduced by nitrite of amyl. At that time I was working a good deal in the laboratory with Gamgee, and knew all about the experiments. I had made none on nitrite of amyl myself, but I was very susceptible to nitrite of amyl, and Gamgee very often tested it upon me, taking traces of my pulse; and then I saw the extraordinary depression in the tension of the pulse which was produced by nitrite of amyl. At that time I was house physician in a hospital in Edinburgh, and there was one poor man in the wards suffering dreadfully from angina pectoris; he used to have an attack every night, and for two hours the unfortunate man would sit on the edge of his bed and could not move forward, backward, or to one side, with his face pale and the sweat pouring off it, in perfect agony. I used to sit by him and try to do what I could to ease his pain. I gave him chloral, I gave him ether, alcohol—everything I could think of. It was all no use. I took tracings of his pulse to see what was happening, and I found that his pulse during the attack became very tense. I tried everything that I could think of, and one day he said, "Well, you have been very good, but it is no use; let me go." I said, "Well, I will try one thing more, and if it does not do you any good you shall go out to-morrow." I went straight up to Gamgee and asked him for some nitrite of amyl, because I thought if nitrite of amyl lowers the tension so much, and this poor man's tension rises during the attack, if I gave amyl it ought to ease him. I brought it back and gave it, and it was perfectly successful. But for the experiments I should never have known the action of nitrite of amyl—nobody would have done so. Richardson's experiments upon himself, you see, simply showed that it flushed the face, that it excited the action of the heart, and produced palpitation; and produced a feeling of giddiness and wanting to sit down, and that was all.

6894. Does not Richardson say, "My description of the effects of the nitrite was that it relaxed the living muscles"?—I suppose that was what he meant to say; I do not think it is in the reports.

6895. Is anything you have quoted incompatible with Dr. Richardson's description of his own researches of 1867, namely, that "the research with nitrite of amyl proceeded in the usual way. I made myself the first victim and tried the effects of the substance by taking it both in the form of vapour and fluid"?—No; he probably tried it, but these experiments would not have helped—his observations did not help at all with regard to angina pectoris.

6896. But you referred to his experiments in your paper of 1867, did you not?—Yes, surely, because it was he who drew attention to the action of the drug. He drew attention to it, and Gamgee and Rutherford followed it up and worked it out, and then I applied it.

6897. (*Chairman.*) How do you trace the benefit of that discovery to experiment on animals?—Because, but for the experiments on animals made by Gamgee and Rutherford, we should not have known that it reduced the pulse tension.

6898. (*Sir William Collins.*) In a letter to the "British Medical Journal" on the 16th of March of this year I see you state that "any benefits which may result to patients from either plan (the inhalation of oxygen or the injection of strychnin) must be regarded as the fruits of experiments on animals"?—Yes, because in regard to strychnin, the first experiments that were really of much use in strychnin were made by Prokop Rokitansky in Professor Stricker's laboratory many years ago. Usually, when you cut the spinal cord across, just at the junction of the head and spine, all respiratory movements cease; but if you inject strychnin beforehand they do not quite cease, and if you inject strychnin afterwards you get certain respiratory movements, imperfect no doubt, but still an attempt at respiratory movement, showing, apparently, there is a certain amount of respiratory centre which extends a little way down into the spine. In consequence of this, one has been accustomed to give it in failure of respiration. Then in the case of the heart, if you tie a ligature around a frog's heart, the junction of the venous sinus and the auricle, it stops; but if you inject a little strychnin into it it will begin again; and if you inject strychnin beforehand, before tying the ligature round, it does not always stop. This appears to me to show—although I daresay Dr. Gaskell may have a different explanation to give of the fact—that the strychnin acts as a stimulant to the heart; and, practically, when we have come to try the result upon patients, we find that strychnin has got a stimulating action in keeping up the respiration and keeping up the heart in cases were both seemed to be about to fail.

6899. I was going to ask you whether the claims you make on behalf of oxygen and strychnin are generally accepted by the profession?—I believe they are.

6900. I notice that on the 23rd of March, this year, in the "British Medical Journal," Sir James Barr seems to speak rather disrespectfully of your discoveries. He says, "Now for Sir Lauder Brunton's other discovery of the use of oxygen and strychnin in pneumonia. I am pleased to think that the craze for cylinders of oxygen is dying out, notwithstanding this spasmodic attempt to revive it." And again he

says, "I rather hesitate to conjecture how many persons have been poisoned by it since that fateful day when Sir Lauder Brunton 'scribbled the other half of his paper in a railway train.'" Perhaps you would like to make a statement in regard to that?—I have heard from a good many doctors since, and they do not agree with Sir James Barr, and they do agree with me. A man of large clinical experience, for example, in Scotland, who has got one of the largest consulting practices in Scotland, as well as a hospital appointment, says that he quite agrees with me and does not agree with Sir James Barr.

6901. I need hardly say, as an old pupil of yours, that I have great respect for your opinion.

6902. (*Mr. Tomkinson.*) I notice that you used the word "narcotised" always. You mean that to be equal to anæsthetised?—It is something more than anæsthetised.

6903. The use of opium, chloral and morphia produces a state of insensibility?—Yes.

6904. Is that at all akin to that insensibility which is produced in a hopelessly drunken person that we see sometimes?—Yes, but to a much greater extent.

6905. But one does occasionally see, unfortunately, people apparently absolutely insensible from drink. Would you say that those people were insensible to pain?—Yes.

6906. Do you mean that although it is almost impossible to rouse them, if an operation were performed on them they would not cry out or show some sense of pain?—Certainly they would not. That observation is as old as the time of Solomon, because Solomon makes the drunken man say, "They have beaten me, and I felt it not. I will go and have some more—I will seek it yet again."

6906A. Then in regard to that case which has been called the baking of dogs, I think it is well it should be absolutely understood that in the case of the first experiment it was merely an artificial external means of keeping up the temperature of the animal while it was under this dose?—Yes, that is so.

6907. And to prevent the loss of temperature, the loss of heat, which is induced by that dose, unless it is kept in by artificial means?—Yes.

6908. And I understand those artificial means were merely external in the shape of a warm foot-warmer and cotton wool?—Yes.

6909. And that it would not be applied to an animal in a greater heat than possibly a very warm bed into which a patient would be put?—Yes.

6910. And could in no case cause pain or burning, or anything to the skin?—No, in no case would it have caused pain, or burning, had the animal not been narcotised.

6911. A process such as that would hardly need any protection from the law?—Those experiments were done before the law was passed.

6912. It would not render the operator or exhibitor of it liable to prosecution for cruelty to animals?—No; but in some of those cases, in addition to this outward case, after the animal was narcotised, a cannula was introduced and warm air was passed in, and then that, of course, became an operation.

6913. Was not that the second series?—The second series.

6914. But the whole statement about this heating never exceeded a temperature of 111 degrees, which the animal was called upon to inhale?—We never reached as much as that. It was the animal that reached that temperature, but the external temperature was never so much.

6915. *Chairman.*) I think it was 106° you gave?—Yes, as the external temperature.

6916. (*Mr. Tomkinson.*) Do you know what the normal temperature of cats and rabbits is?—The temperature of the rabbit is an exceedingly variable thing; it has very little power of preserving a steady temperature; I speak under correction by Dr. Gaskell, but my impression is that it runs practically from about 100° to 104°.

6817. Rather higher than in man?—Yes, and in pigeons it is about 104°.

6918. You do not often use curare?—No, I have very rarely used it. I do not think I have used it at all since the passing of the Act, because I always had the feeling that curare alone might not completely destroy sensibility. I may, perhaps, mention that I was very anxious to find that out, and when I was in Leipsig in 1869, I proposed to Professor Ludwig to give me curare, and then, perhaps, apply a hot iron or something to the back of my hand, and keep up artificial respiration till I came to life again; and then I would tell him whether it would hurt or not; but he said that the risk was too great, that the means of keeping up artificial respiration were not sufficiently good, and he thought it was not worth while to do it—and he did not do it.

6919. With regard to inspection, you are not favourably disposed to increased inspection?—No, I do not think it would do any good.

6920. Have you seen a letter, in "The Tribune," I think it was, from Miss Lind-af-Hageby, headed "Vivisection and Inspection"?—No.

6921. She writes that while in the years 1903, 1904 and 1905, the number of experiments performed was 89,581, the united labours of the two inspectors led them to witness 93 experiments only, leaving the cost to the country, taking their salaries, 2,550 guineas, whilst 89,488 experiments were left uninspected. That shows a very small fraction of inspection of the experiments that take place. Now, in regard to inspection by the public, we will say, would it not be well, do you think, in order to set the public mind at rest, from your point of view, that there should be some right of entry by authorised people occasionally to witness experiments?—I do not know that it would.

6922. What would be the objection?—The objection would be that they would describe things in a way that was coloured by their own imagination. In the same way as they misstate what I have done with regard to warming animals, so they would be apt to describe any experiments in a falsified way.

6923. I did not in the least mean a newspaper reporter for the sake of copy, but, say, medical men, or perhaps Members of Parliament, on presentation of their card?—No, I think that anyone who wanted to inspect should be authorised. There would be no objection to having them if they applied to a central authority, the Home Office, and the Home Office thought they were right and proper persons to see them—then, by all means, let them go. But it should not be merely on presentation of a card. The Home Office should be certain that the person was a right and proper person to go and see the thing, and then, of course, there could be no objection whatever.

6924. (*Chairman.*) I will go back now to the general line of your evidence. I will leave out those matters which you have already dealt with in answering the members of the Commission who have been examining you. It has been suggested to us by several witnesses that the results of experimenting on animals and relying on the results of experiments has dulled the edge, as it were, of clinical observation, and that doctors do not now give the same attention to clinical observation that they did before. Have you formed any opinion as to whether that is so—do you think it has made any alteration whatever in the zeal with which a doctor pursues his clinical observations when he is attending a patient?—I do not know that that is so. Experimentation on living animals has given doctors so many more means by which they can readily ascertain things assuredly, that perhaps in some respects they may be said not to have the same zeal as before. To take an example unconnected with experiments upon animals, formerly a doctor had to depend entirely for his knowledge of fever upon inspection of the tongue, the feeling of the pulse, and the feeling of the skin. Now, instead of taking so much trouble with the pulse and skin he not infrequently just puts a clinical thermometer into the mouth; he reads off the temperature precisely, and he knows exactly what the fever is. He does that, of course, in less time and with less trouble, and he prefers to do it in that way. Perhaps if there were two doctors, one of whom was accustomed to trust to the thermometer and the other had never known of the thermometer, and they were put down by the bedside of a patient, if the doctor who used the thermometer had broken his thermometer he would not be so good as the man who had never used one.

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

6925. But taking the whole knowledge and instruction of doctors together and assuming what you say about clinical observation, do you think that their power of dealing with disease has increased or the reverse?—It has increased incomparably; and I can speak to that because I came in just at the time when the change was beginning. When I was a student there were no remedies for producing sleep except opium, henbane, and tartar emetic. When a man had no fever on him we gave him opium or some henbane; and if he had fever we gave him opium and tartar emetic. I remember perfectly well when I was house physician one of the other house physicians got ill with typhus, and he was very sleepless, and we watched with great interest the introduction of a new remedy, bromid of potassium, to see whether it would give him any sleep. Since that time we have had any number of drugs to produce sleep. We have got chloral, veronal, sulphonal, and trional, and a whole lot of others, and we can now produce sleep in a way that we could not dream of doing before.

6926. Was bromid of potassium discovered by experiments on living animals?—I do not think so—it is a rather difficult thing to trace how it came into use. My own belief is that it came in rather by chance observation upon men.

6927. Were these other soporifics to which you have referred discovered by experiments on animals?—Entirely.

6928. Have they the same kind of operation as bromid of potassium to the same extent, or have they advantages over it?—They have considerable advantages. Bromid of potassium is more of a general nervine sedative rather than a sleep producer. These others are distinctly producers of sleep or soporifics, and they have all been made upon definite principles. They have all been tried upon animals, and have been introduced in consequence of experiments upon animals.

6929. And in those experiments on animals is the object first to discover the effect—whether they cause sleep, and then to discover also what is a safe dose?—Yes, both those things.

6930. And are experiments of both those kinds necessary before you venture to try them on mankind?—Yes, absolutely; because the life of an animal is so much less valuable than the life of man, and we cannot afford to test these things upon man.

6931. That is only an instance that you have been giving us in the matter of producing sleep; but I was asking you a general question, and I think you answered it in the affirmative, that you thought there had been a great improvement of knowledge?—An enormous improvement.

6932. Do you see any reason to suppose that that increase of knowledge would have come from mere clinical observation without experiments upon animals?—No. One may say that it certainly would not have come, because clinical observations have been carried on for very many centuries, and have led to nothing. Taking again the case of sleep, clinical observation has been carried on for millions and millions and millions of years, and all that time opium and henbane and tartar emetic were the only results; whereas in 50 years we have got any number of new drugs.

6933. Leaving out the question of surgery?—I am speaking only of the question of hypnotics or soporifics.

6934. But my question was rather general—would your answer apply to general medical knowledge?—Yes.

6935. And surgical knowledge?—And surgical knowledge as well.

6936. You refer in your *précis* to the value of various discoveries by experiment, with which I need not trouble you, because we have heard of them from several witnesses—Harvey's discovery of the circulation of the blood followed by others afterwards. With regard to the diagnosis of cardiac disease is that a thing in which experiments on animals have improved knowledge?—Our recognition of heart disease is based upon the change in the cardiac sounds. The explanation of those changes was first afforded by a Committee of the British Association who made experiments on animals and ascertained definitely that certain alterations in the cardiac sounds were associated with definite changes in the valves of the heart, and it is to those experiments that we owe our power of recognising the presence of cardiac disease.

6937. What was the date of that Committee?—1836, I think.

6938. Then in the treatment of heart disease, has advance been made in consequence of experiments on animals?—One may say that the whole treatment of heart disease is really dependent upon the results of experiments upon living animals.

6939. Both as to drugs and as to regimen generally?—Yes, in regard to drugs especially one may say. When I was a student digitalis was regarded as a drug which would weaken the heart, and was to be avoided in all cases of cardiac weakness, whereas now we know that digitalis is an extremely powerful tonic to the heart, and we use it in cases of cardiac weakness instead of avoiding it.

6940. I do not know whether you have had an opportunity of reading the evidence which Dr. Cushny gave before us?—Yes.

6941. Do you agree with his evidence about digitalis?—Yes.

6942. Then I need not take you into it at length, because he went very elaborately into it?—Quite so.

6943. Is the study of blood pressure in the blood vessels a matter of great importance?—It is, I think, a matter of the utmost importance in regard to the prolongation of life, because it is just when a man has gained most experience and has got the widest power that he very often begins to fail, and very often dies off suddenly, or to suffer from some condition of the heart which prevents him from taking any active part in life. The condition which arises with advancing years is one of increased tension within the vessels. We can now recognise that tension by means of instruments which have been worked out in consequence of experiments upon animals; but this would be of little use to us were it not that by means of drugs, which have also been worked out by experiments on animals, we are able to reduce this tension and to keep it down so that we are able to preserve lives for many years after they would otherwise come to an end.

6944. Why do you say that you discovered the state of tension by virtue of experiments on animals?—Because it is only by experiments upon animals that we have learned anything about the tension inside the vessels. The first experiments upon this point were made by the Rev. Stephen Hales, under the auspices of the Royal Society. He put a tube into the carotid of an animal and saw how far the blood mounted in the tube.

6945. We need not trouble you with regard to that; we have had it gone through?—But shall I explain the practical value of it.

6946. If you please?—When you take the blood pressure of a man (I wish I had brought the instrument down; it is very easily done; you can take it in half a minute now), if you find that the blood pressure is low, you can give the man a tonic which will act on his heart and vessels and raise the temperature up to the normal, thus increasing his power; but if you find that the blood pressure is above a certain tension, then you know that that man is liable either to have a vessel give way in his brain, and so to become paralysed, or to have the tension become too high for his heart to withstand, and then the heart begins to fail and stop, or he gets angina pectoris. In such a condition you can put him upon a diet and upon medicines which will lower his tension and keep it at the normal, thus preserving his life or preventing either the paralysis or the cardiac pain which would otherwise come on.

6947. I think you have already explained what you have to say about the effect of nitrite of amyl on angina pectoris, in answer to Sir William Collins?—Yes.

6948. I need not ask you any further questions about that. As regards dropsy, have there been considerable discoveries made in consequence of experiments on animals?—Yes, because through experiments on animals we now know that we can influence dropsy in more ways than one; that we can influence it through the blood vessels by preventing too much fluid being passed out, or we can influence it through the kidneys by causing them to secrete more freely, and we can influence it also by drugs which act upon the com-

position of the blood and prevent exudation from the vessels.

6949. These are things that you have learned to do since the beginning of the era of experiment?—Surely. These have all come within the last fifty years.

6950. These are remedies which had not been discovered so far by clinical observation?—That is so.

6951. I do not know whether you have said all that you wish to say about respiratory stimulants and strychnin?—I have said all I wish to say about that.

6952. I think you wish to tell us something as to abdominal surgery?—I regard abdominal surgery, really, as starting with some experiments upon animals. The first experiments that were made from which one can trace more or less continuously the present use of surgery in abdominal disease were the experiments of Ludwig and Thiry, who were investigating the action of intestinal juice. They cut out one piece of intestine and sewed the ends of the cut intestine together, making a continuous tube, leaving one part out.

6953. These were experiments on animals?—Yes. These experiments were continued for a long time, more or less, only in the laboratory, and then they were taken up by the surgeons, more especially by one of the Viennese surgeons, Billroth, who did a great deal in that way, and I think that Billroth's taking them up was really due to the influence of his colleague Professor Stricker, Professor of Pathology.

6954. And have these experiments made possible that and other operations in the intestines which were not possible before?—Yes, of course.

6955. (*Sir William Church.*) You would not say that directly; you would not say that those operations alone have made that possible; there have been others?—I meant that those were the starting point; and from those, I think, you can find a regular succession.

6956. (*Chairman.*) Of experiments of the same kind in that direction?—Yes.

6957. (*Sir William Church.*) That must be taken in connection with Listerism, for instance?—Experiments made before Listerism are like operations before Listerism; they would very likely be unsuccessful, and it is only since the introduction of antiseptic precautions that these experiments have been done very much in the laboratory or elsewhere.

6958. (*Chairman.*) I do not think it is necessary to ask you upon every one of these particular instances that you give, but you attach great importance, I gather, to the result of experiments with regard to myxedema and cretinism?—I do.

6959. Would you tell us what you have to say with regard to that subject?—I thought that had been taken up by some of the other witnesses. I do not know that I can give you such a connected history of myxedema and cretinism as some other man would, Sir Victor Horsley, for example, but practically it was found that the removal of the thyroid gland produced a condition in which cellular tissue became thickened and the animal became enfeebled; and in cases where that was done in man it produced a condition of imperfect action of the mind resembling those cretins who used to be found so commonly in some of the Swiss valleys; so that the function of the thyroid gland became connected with this condition of the thickened connective tissue and stunted growth and feeble development of the mind. It was then found that by giving the thyroid gland in this condition, especially to children, the feebleness of mind disappeared, the child began to grow, and at once the dwarfed idiot began to develop into a perfectly normal man or woman.

6960. Has this remedy of the thyroid gland been tried in the Swiss valleys, do you know?—I do not know. I have no doubt it has; but I should think there must have been something else that has led to the disappearance of the cretins; because 50 years ago in the Zermatt Valley you found the whole place crowded with them, with those enormous goitres; and before the introduction of the use of the thyroid these had to a great extent disappeared, so that there must have been some other factor, though I do not know what it was, which led to the disappearance of cretinism in those valleys. But this condition of myxedema now is very commonly recognised at once, whereas it was not recognised before, and we find that in almost every case now we are able to remove it, for a time at least, by the administration of thyroid gland.

6961. (*Mr. Ram.*) How is it used—hypodermically?—No; at first it was given hypodermically, but then we found it could be given perfectly well in tabloids, or the extract of the gland in solution could be taken internally and produced all its effects.

Sir L. T. Brunton, M.D., F.R.C.P., F.R.S.

6962. (*Chairman.*) I forget from what animals the thyroid is taken?—I think generally they take it from the sheep. 24 April 1907

6963. (*Sir Mackenzie Chalmers.*) From sheep killed in the ordinary way?—Yes.

6964. Immediately after death?—Yes, immediately after death—I believe so; but I am not quite sure whether other animals may not be used instead.

6965. (*Chairman.*) Some witnesses have made a great point—I do not know that it has been supported by any very precise evidence—of the danger of introducing the materials which form part of another animal into the human body, some upon the ground that there is something abhorrent to the feelings in it, and others that it gives to the person who takes that remedy some part of the susceptibilities of the animal which to some extent affect the mind and body of the person according to the animal from which it was taken. Do you, as a scientific man, see any foundation for that?—No. Of course the whole idea of eating meat at all is to many people abhorrent, but otherwise I do not see anything in it.

6966. You do not see any difference between eating a slice of a leg of mutton and some of the thyroid gland, as far as that argument goes?—No.

6967. Does it make any difference as to whether you give it through the mouth or injected into the body?—Yes, in some cases at least. For example, the blood of an animal cooked which you take into the human stomach is digested there and does no harm; but if it is injected into the carotid or into the jugular vein it would do harm. That is the reason why the old plan of infusing the blood of animals into man was given up. But there is no other reason for supposing that there is any special action.

6968. Of course it is very much the same as the objection taken to vaccination from a healthy calf?—Yes.

6969. From an unhealthy one, I suppose there would be an objection?—Yes. And then, of course, one does not like to say, that in a very widespread superstition there may be no element of truth; because we find that cannibals believe that if they take the heart of a strong man and eat it, they get his strength going into them; and the Hottentots and other uncivilised nations are very fond of eating the heart of a lion, so as to gain the strength and courage of the lion; so there may be something in it, but I do not think there is a great deal.

6970. I see you say that one of the most important inventions in regard to the relief of pain, may be considered to be the introduction of hypodermic medication, which is the result of experiments made upon animals?—Yes.

6971. I do not quite follow that. It would seem to one that there is nothing in this that could not be done by clinical observation?—It is quite true.

6972. That any hypodermic injection might serve the purpose, instead of swallowing?—The way it came about was this: Sir Robert Christison was a student of Orfila's in Paris, and Orfila made a very complete series of observations on the action of all kinds of drugs upon animals, which he recorded in his Toxicology. Sir Robert Christison was a pupil of Orfila's, and used to talk a good deal about Orfila and his experiments; he talked about them to old Dr. Alexander Wood, and Alexander Wood somehow or another thought that instead of using the intravenous injection of which Orfila was so fond, if he injected into the subcutaneous tissue he would get the same result; and he tried it, and it answered; and that is how it came about. I do not know whether Dr. Alexander Wood published definitely this, but what I am giving you now is the result of what I used to hear when I was a student, when I knew Christison, and slightly knew Wood.

6973. (*Sir William Church.*) Of course the improvement in chemistry had something to do with it?—Yes, undoubtedly.

6974. But it would not have been possible for Orfila to have made use of many drugs which are now used hypodermically, because their active principles had not been extracted in the shape that they now are?—No,

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907

but at first when Wood introduced the syringe it was employed almost entirely for morphin.

6975. Now, of course it is used for many other drugs besides morphia, and do you think with advantage, for instance, quinine in cases of malaria?—Yes.

6976. And also mercury in cases of syphilis?—I do. In the cases of malaria especially one knows that there are certain cases that do not yield to quinine given by the mouth, and do yield to quinine given by the hypodermic syringe. In regard to syphilis I have very little experience, because I do not see many of those cases, and I have no experience whatever in the case of mercury hypodermically given.

6977. In certain maniacal cases it is sometimes useful when you would have great difficulty in getting the patient to take the drug by the mouth?—Yes. In such cases it is of the utmost service, because the injection of a very small dose, even the hundredth of a grain of hyosin will probably quieten them down.

6978. Also apomorphia in certain cases of poisoning?—Yes, in such cases you can get active vomiting in a very short time, quicker than you possibly could do it otherwise.

6979. (*Sir Mackenzie Chalmers.*) By subcutaneous injection?—By subcutaneous injection; and then, of course, in the case of a bit of gristle just sticking in the throat and gradually choking the patient, if you can inject hypodermically apomorphin and get him to vomit, the gristle will be ejected.

6980. (*Chairman.*) Then with regard to experiments for the purpose of teaching, what is your opinion about that?—I believe that in order to thoroughly teach youths physiology and pharmacology in the way they ought to know it, you must have experiments. I have had both kinds of training. When I was a student no experiments whatever were shown, and I learnt my physiology from text books and from diagrams. I then went across to Germany and learnt it there by demonstration; and the difference between the two is just as great as learning how to put on a splint by reading an account of it in a book and doing it yourself. You get a practical notion of your physiology from demonstrations that you cannot possibly do from lectures.

6981. It cannot be done by anatomising?—No, it cannot be done, because anatomy deals only with structures, and physiology with the living functions.

6982. You approve of that course being followed?—Assuredly. If there was any pain involved to the animals, I should say that we had better not do that; but as it is a question where there is absolutely no pain involved to animals and a great deal of advantage to be gained by students and thereby a great deal of pain, I believe, saved to patients afterwards, I think it is the bounden duty of the teacher to give demonstrations.

6983. You think that anæsthetics ought always to be used?—Surely.

6984. (*Sir Mackenzie Chalmers.*) You would not allow the animals to recover, as I understand; you would limit it to operations where the animal was not allowed to recover?—I am not sure of that.

6985. (*Chairman.*) I believe you yourself were a witness before the 1876 Commission?—Yes.

6986. So far you are the only witness before that Commission who has appeared before us?—The others are dropping off.

6987. (*Mr. Ram.*) You say in your *précis* that when you were carrying on your investigations you were cut short by the difficulties occasioned by the Vivisection Act?—Yes.

6988. What was it in the Vivisection Act that squeezed your experiments out of existence?—The difficulty of getting a licence for a number of experiments without anæsthetics. You see, in order to investigate the action of snake poison, the injection of snake venom was requisite. This was looked upon as an experiment, and an injection of or application of the permanganate of potash by an incision was also looked upon as an experiment without anæsthetics. Of course the amount of pain inflicted was very small indeed; but then it was regarded as an experiment without anæsthetics; and the difficulty of getting leave for a sufficient number of such experiments was great, so great that we had really to give it up.

6989. But you were able to take to it again in 1904?—Colonel Rogers then did the experiment, but he was able to do it in this way: that in the interval Professor Waller had invented an apparatus by which chloroform anæsthesia could be maintained without interruption mechanically for 30 hours or more; so that Colonel Rogers was then able to do the whole thing under anaesthetics, and of course there was no difficulty in receiving a licence to do a number of experiments under anæsthetics.

6990. I am obliged to you; that answers that point. You say also in your précis that it seems to you that the law against experimentation ought to be very much relaxed?—Yes.

6991. Are you able to indicate in what direction you would relax it?—I should allow greater freedom, I think, in regard to experiments in which no actual pain is inflicted, for example, such as the inoculation experiments. It is simply inoculation of a microbe, but there is no actual pain; the experiment itself is really devoid of pain. These are now becoming among the most important of all the experiments; and in regard to them I should allow much greater freedom. I should not regard many of them as experiments at all. Perhaps I may just mention the view of the late Professor Huxley. He said to me one day—he was then a member of the Fisheries Commission: "If I take a live minnow and put a hook right through it, and then spin it round alive until I catch another live fish, and I pull the live fish, after many struggles and a length of time, out of the water, I am perfectly entitled to do that because I do it for sport; but if I scratch the nose of a salmon for the purpose of ascertaining the nature of the salmon disease, I am making an experiment, and if I have not got a licence I am liable to a fine of £50."

6992. Then as regards your relaxation that you were speaking of, in that direction would your wishes be met if a number of experiments of this non-painful nature were allowed; and would you still retain the law as at present, that that can only be done by a licensed person on licensed premises?—No, that is just where the difficulty arises, where you have a combination of a licensed man and a licensed place. If you license a man you might let him experiment in an unlicensed place. For example, other witnesses can tell you much more about it, but I believe the examination of grouse disease by a licensed man is rendered exceedingly difficult, or almost impossible sometimes, by insisting also upon a licensed place.

6993. We have had that case brought before us?—So I should say practically that if you licensed the man or the place, an experiment done in a licensed place under licensed supervision even by an unlicensed man might be allowed, or done by a licensed man giving a proper report in an unlicensed place.

6994. Would you limit that to experiments strictly non-painful?—No.

6995. The experiment might be painful and you would ask that it should be done by a licensed man, either in a licensed or an unlicensed place, or by an unlicensed man, provided the place was licensed?—Yes, that is the position I take.

6996. Are you aware of the state of things in America to-day?—I know that in many places there is a great agitation being got up, very much the same as in this country.

6997. In favour of what?—In favour of anti-vivisection.

6998. Do you know that there is a large body there of scientific men who are asking not to have no regulation on vivisection, but to have exactly such an Act as we have here?—No.

6999. I think I have only one other matter to trouble you with. In your *précis* you say that it is through experiments on animals also that the nature of the most dreadful of all respiratory diseases, namely, phthisis, has been discovered, and that we have already begun to lessen, and you trust ere long will stamp out the disease. Can you elaborate that a little? What is being done with regard to ascertaining the nature of phthisis?—That has now been ascertained to a very great extent indeed. We now know that phthisis depends upon an invasion of the lung by a certain bacillus, the tubercle bacillus; that in many cases, however, the infection is not a pure infection but a mixed infection. That there are various other microbes associated with the tubercle bacillus, and

which aid its invasion of the body. But if we could simply prevail upon all people to recognise the infective nature of phthisis, to prevent spitting in all public places, to take proper precautions against the conveyance of the tubercle bacillus from one individual to another, in 30 years phthisis would be just as rare in this country as leprosy is now.

7000. Is that true also of all tubercular disease?—I believe that all tubercular disease could be stamped out entirely in this country in 30 years. The chief objection to it is the expense; because in order to stamp out tuberculous disease, you would probably require to slaughter a large number of cattle; and that is the crux of the matter in regard to animals, and in regard also to the tubercle, more especially in the abdomen of children.

7001-3. Is it your view that tubercle in the abdomen of children is contracted from cattle, from milk?—I think so.

7004. (*Sir Mackenzie Chalmers.*) From milk or meat?—I believe it is much more from milk; because the heat that is used in thoroughly cooking, either by boiling or by roasting meat, is sufficient to destroy the vitality of almost all bacilli; and milk is a vehicle in which bacilli can be conveyed, because it is almost always used without being sterilised.

7005. (*Mr. Ram.*) I think I understood you to say that the use of bromid of potassium as a sedative came in, you think, from clinical observation?—I think so; but I am not quite clear about it.

7006. That was after the lapse of centuries of clinical observation?—Bromid of potassium was really only a more or less new product.

7007. Has the use of useful drugs which are now commonly used increased very largely since experimentation came in?—I do not quite know that I follow that question.

7008. What I mean is this: Of course, all drugs in the days before experimentation on animals came in by clinical use?—Yes.

7009. And it took a long term of years to get a certain knowledge of a certain number of drugs?—Yes.

7010. Has the use of drugs which have turned out to be useful been very much more rapid; has there been a large number of drugs added to the repertoire of useful drugs since experimentation on animals?—Yes, the increase in the number of useful drugs added to those which were formerly employed has been very great since the introduction of experiments on animals.

7011. Has experiment upon animals also had this effect, that it has given an accurate knowledge of previously known drugs of which the use may have been mistaken before that?—Yes.

7012. (*Sir William Church.*) With your experience should you say that there was any difficulty in keeping animals under the influence of anæsthetics for lengthened periods?—None whatever.

7013. Not in the case of dogs?—No.

7014. Do you think that physiological experiments, not directly connected with medicine, have been of great value to medicine?—Yes, an enormous advantage. Many of the experiments which have had apparently little or no connection with medicine at first, have turned out really, afterwards, to be of the utmost possible value.

7015. You remember, perhaps, the way in which chloral was discovered?—Yes, I do.

7016. Do you think it is not probable we should have arrived at the use of chloral if it had not been for Liebreich's experiments?—No, we certainly should not.

7017. That was one quite unconnected with practical medicine—his original experiment. I will not trouble you with it, because we have it from Professor Cushny; I only wanted to get confirmatory evidence; but his original experiments had nothing to do with practical medicine?—They were originally intended more from a scientific point of view. It was from the scientific point of view that he started.

7018. And the action of sulphonal in the same way, I think, was not found out by experiments directed towards practical medicine?—No, it was incidental; it came out in a by-issue in some other experiments.

Sir L. T. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

7019. Was not also the same the case with regard to antipyrin and antifebrin?—No, those, I think, were really the definite results of experiments made on animals upon definite lines. The starting point of the connection between chemical constitution and physiological action was really, I think, in modern times made by Dr. B. W. Richardson. Somewhere about 1844, Dr. James Blake, under Dr. Sharpey's direction, made experiments on the relations between physiological action and chemical composition; but then there was a great lapse of about 20 years, and then Dr. B. W. Richardson took up the chemical series of the alcohols, showing that there was a relationship between the chemical constitution and the physiological action of the different alcohols. Following upon this came the experiments of Crum Brown, and Fraser, who found that if you alter the chemical constitution of strychnin by the introduction of methyl, its physiological action becomes altered, and instead of becoming a convulsive poison it becomes a paralysing poison, like curare. Then after that followed a number of experiments with the benzine compounds, and it was found that many of them had the power of lowering temperature. A series was then produced of synthetic chemical compounds of the benzine series. These were tested, and various of them were found to be practically very useful antipyretics.

7020. To interrupt you for a moment, was not the idea of the original experiments of antipyrin that it was antiseptic rather than antipyretic; that it counteracted septic fever in animals and fever produced artificially in animals?—It is quite possible that you may be correct, because the antipyretic and antiseptic actions are very closely combined in the benzine series; so that—I cannot quite recollect it now, I have not looked up the subject—it is quite possible that they were working on antiseptic lines, and found that the antipyretic power was the one most definitely pronounced. But those two lines run quite parallel; so that now we have got a great body of artificial antipyretics and antiseptics produced which are all made by the trained chemists who prepare these substances on definite chemical lines, and then they are tested physiologically upon animals. If they are found to be satisfactory they are then used upon patients.

7021. Could you tell us how cocain came to be introduced into medicine?—So far as I can recollect now, Von Anrep was the first man to introduce it.

7022. Is it not the case that he was experimenting for physiological purposes rather than for a practical end?—Yes.

7023. Up to that time cocain was not known as an anæsthetic, but as a stimulant enabling fatigue to be borne?—That is so.

7024. (*Colonel Lockwood.*) Do you say that that was the case?—Yes.

7025. That he was experimenting for other purposes?—Yes, physiologically. The first experiments upon cocain which might lead to a knowledge of its anæsthetic action really were made by the late Dr. A. Hughes-Bennett and Professor MacKendrick, because they demonstrated that it destroyed the power of sensory conduction in the cord; but for some reason or other these experiments were not followed up, and it was Von Anrep who actually gave the first actual impetus to the introduction of cocain into the practice of medicine.

7026. (*Sir William Church.*) Then he was followed by Koller, who made use of it for ophthalmic purposes?—But if I remember rightly it was used only for ophthalmic purposes in man after it had been previously tested on the eyes of animals.

7027. And now local anæsthesia for which cocain, or eucain, or one of the similar bodies is used is a very important addition to medicine?—Yes, it is, and in addition to that purely local use, it is now being used by introduction into the spinal cord, which is a form of use which is rather based, one would say, upon the very old experiments of MacKendrick and Bennett.

7028. With regard to some experiments which have been mentioned in this room by witnesses on both sides, experiments upon digestion and upon the passage of food down the intestines, it has been stated here that all that was of value was learned by Dr. Beaumont from the examination of the stomach of Alexis St. Martin. How far do you think that is true?—That is not correct, of course. Dr. Beaumont's experiments were very valuable indeed, because it was

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

a case of experiment upon man. The side of poor Alexis St. Martin was blown away by a charge of duck-shot, so that they could see inside, and Dr. Beaumont made very good use of his opportunities; but that only went a very short way. It showed that the gastric juice had the power of digestion; it showed that when Alexis St. Martin drank too much spirits his stomach got very much out of order, and that was about the end of it. Dr. Beaumont also found that if he stirred up the stomach very much with a glass rod, or something of that sort, Alexis St. Martin might feel a little sick; but the whole of the rest of the practical introduction of such things as pepsin, pancreatin, and all the adjuncts to digestion have resulted from the experiments upon animals, made afterwards by Blondlot, by Bernard, Bedder, and Schmidt, and others, and the most recent have been made by Pawlow.

7029. In your opinion is gastric fistula in an animal or an intestinal fistula in an animal a condition in which it suffers great pain?—Certainly not.

7030. You say that confidently?—I say that confidently.

7031. Why do you speak so confidently?—Because years before the Act I made a gastric fistula in an animal, in a dog, which never showed the slightest sign of pain, and when I wanted to examine inside the stomach it showed great delight—just like a dog that has been sitting about the house and wants to run out for a walk. When it saw that I was going to look into its stomach it frisked about in the same way as if I was going to take it out for a walk.

7032. (*Colonel Lockwood.*) How did it know what you were going to do?—Because I did it day after day. I made the fistula and the fistula healed up. Then I had a cannula in the stomach and corked it up so that I could look in.

7033. I confess that I am rather aghast. If I understand you rightly—I do not want to do you injustice—the dog showed great delight when you were about to perform an operation on its stomach?—No, after the operation had been done and the thing was healed up, when I wanted to examine it it seemed delighted.

7034. Because it afforded it relief, I suppose?—No, it was because it liked to be made much of and petted and shown round.

7035. (*Sir Mackenzie Chalmers.*) It liked to be taken notice of?—Yes.

7036. And there was no pain?—There was no pain. Practically, one knows there is no pain afterwards. For example, just two days ago a celebrated surgeon did an operation upon a patient whom I had seen because the patient was then suffering from cancer of the œsophagus and could not eat. The patient was almost dead when he came to the surgeon, who then injected into his veins a quantity of saline solution. He was brought round sufficiently far to do the operation, and then, having got it done, he poured into his stomach a lot of nutriment. The patient is now very comfortable and has no pain after the operation. I have no doubt, if you are at all doubtful about it, that I can get a certificate from the patient.

7037. I will take it from you, of course.

7038. (*Sir William Church.*) As a matter of fact, in men, is the opening of the stomach a very painful operation?—No.

7039. In fact the actual opening of the stomach is usually done without any anæsthetic at all being administered. The attachment of the stomach to the wall is done under anæsthetics?—Yes.

7040. And after the stomach has been opened the patient seldom or never experiences pain in the passage of the tube into it for food?—That is so.

7041. You answered some questions about myxedema, but it is stated now by anti-vivisectionists that iodin used to be given before any experiments were made on the thyroid, and that it was a cure for the condition of myxedema or cretinism, or, at least, that it has acted beneficially. I should like to know your opinion upon that?—It is quite possible that it might act beneficially, but it certainly was not a cure.

7042. And now the same effects that were obtained by feeding with thyroid gland can be got by a substance which is called thyroidin, which is, of course, obtained from the gland. Do you know anything about it; or would you rather not say anything about it?—I do not quite see how that bears upon the question one way or another; because the use of thyroidin is as much derived from experiments upon animals as the use of the thyroid gland itself.

7043. It is really not a true distinction; it is a mere play upon words?—Simply a play upon words.

7044. Have you turned your attention at all to the value of experiments on animals in connection with preventive medicine?—No, that is such a very large subject.

7045. I meant, rather as a means of diagnosis, have you turned your attention to that. We have been told here by an authority that the surest and the best method of diagnosing the presence of certain diseases that may be imported at our ports is by inoculation experiments in plague, cholera, and such like?—I cannot give you any definite information about that. It has not come in my way.

7046. Do the answers that you gave to Mr. Ram cover all that you would like to say with regard to the restrictions that the Act imposes upon experimentation upon animals, or would you like to add anything more? I gather from your answers to him that you are in favour of allowing persons who hold a licence to experiment where they like?—Yes.

7047. And, on the other hand, that persons who did not hold a licence might experiment in licensed laboratories?—Yes.

7048. But I suppose you are in favour of the present law, that no one should do experiments upon animals excepting the holder of a licence or in a licensed place?—Surely.

7049. Do you think there are no restrictions further that you would like to see removed? Are you satisfied with the present licences and certificates?—Perhaps, in regard to that, I am rather at a disadvantage, inasmuch as I have not been able to work under licence or certificate for some time, so that those in more active work than I am could probably give a better answer. So far as I am concerned, I think the licence and certificates are all very well. I do not know that I should advise very much alteration except in the way I have mentioned.

7050. You do not think that the having to get special certificates such as are now required interferes seriously with the work in scientific laboratories?—To some extent it does, as I found in my own case when, some two years ago, or rather more, I gave a course of lectures on the therapeutics of the circulation at the London University. I did not allow sufficiently long a time for obtaining a licence and a certificate to show experiments under anæsthetics. The consequence was that when I began to give my lectures I found that I had got over a considerable extent before I got any licence or certificate, and the result of that was that I was unable to go on in the regular sequence. That disturbed me very considerably. The delay in that case was of very considerable importance, and disturbed very considerably the lectures I should hav given. If I had been able to get a certificate and licence at once, say within a few days, it would not have mattered, but, as it was, I was kept waiting a considerable time—I forget exactly how long; I think between a fortnight and three weeks—and it was very inconvenient.

7051. But still you would not press for such a point as this, for instance: that a person holding a licence should be freed from the necessity of getting certificates for experimentation on certain classes of animals and for keeping animals alive after experimentation?—I think if you have got a licence as a recognised good worker it might be at once endorsed: "This licence carries with it the liberty to work upon such and such things." That would greatly free a man, for this reason, that every now and again, in every research, a question crops up, and you wish to get that question answered; if you have to wait to get a special licence before you can tackle the question the opportunity for answering it has sometimes gone; so that if, instead of requiring special licences on every occasion, the licence simply carried with it, "This licence allows the operator to do so and so," at the very beginning, that would greatly lessen the hampering of research.

7052. (*Colonel Lockwood.*) How long do you suggest that licence should last?—I think a year.

7053. (*Chairman.*) Then you dispense altogether with the intervention of any medical body or authority who

has to approve the certificate as being for a proper reason?—It would not be necessary then.

7054. It would not be necessary, because you would have dispensed with it by the licence?—I take it that this certificate would not be granted without previous inquiry into the candidate's qualifications.

7055. Yes, but you make it simply a question of qualification, and having got a man who is qualified to hold a licence you would have him qualified to perform operations which now require a certificate—that is to bring the animal to life again without killing it?—Not necessarily. You might have a simple licence, and then if the experimenter thought that he foresaw the possibility of requiring something more, he might at once indicate beforehand the probability of his having to do certain experiments, which could be then submitted to the proper body, and with their sanction a certificate could be given.

7056. That is qualifying a good deal what you said before?—That is really what I mean. I did not think of a licence being granted simply to everyone, with the idea of his doing everything he pleased. I did not think that a licence carrying the power to do everything should be given to every applicant, but that when the applicant had a plan before him, involving the probability of various extensions, he should put down, as he is required to do now, I think, what he wants the licence for, and that in the event of his probably needing extensions, these could be at once granted beforehand to him in the licence, instead of his waiting until the need arose, and then applying for a special certificate.

7057. You would add to the present Act, without repealing the present provisions, a clause granting a special licence in a particular case, with special privileges as regards operations that might arise out of a particular leading operation?—Yes.

7058. (*Dr. Gaskell.*) You meant rather, did you not, that this special licence should only be given to well-tried men?—Surely, to trained men to be approved by somebody, as at present.

7059. (*Sir William Church.*) I only want to ask you one other question, and that is this: Do you think there is the slightest ground for saying that the witnessing, or the performing of experiments on living animals in any way affects the character of the spectator or the operator?—No, there are no grounds whatever for it. I may say that there are no more grounds than for believing that looking at operations on patients blunts the susceptibilities of man. My own belief is that, whereas surgeons who have been accustomed to see and to do surgical operations, have less of the hysterical element about them, and do not faint or become helpless at the sight of the suffering and pain of others; they have become on the contrary much more tender-hearted and much more willing to put themselves to a great deal of inconvenience, and to sacrifice themselves in order to save pain to others; and I believe that there is no more injury done to the moral faculties of the students who see experiments performed simply in order that they shall learn how to give relief to their patients than there is when they see the surgical operations done to give relief to their patients.

7060. (*Sir Mackenzie Chalmers.*) To follow that up, I suppose that when a man faints at seeing an operation, it is really because he is sorry for himself, and not because he is sorry for the patient?—Yes.

7061. And when he gets used to it, it ceases to affect his own nerves, but it does not affect his feeling for the patient?—That is so; that is very truly put.

7062. You are a Fellow of the Royal Society as well as a Fellow of the Royal College of Physicians?—I am.

7063. How long have you been a Fellow of the Royal College of Physicians?—About 30 years, and I have been a Fellow of the Royal Society, I think, for 33 years.

7064. In this inquiry we are anxious to get evidence from both sides. Can you give us the name of any Fellow of the College who could give us evidence against the view that you have been taking to-day?—No, I do not know of any; of course, there might be such.

7065. But you do not know any one whom you could suggest to us?—No.

7066. Now I want to go more into general questions. There is a great deal of feeling, naturally, about dogs. If experiments on dogs were prohibited would medical science suffer?—Yes.

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

7067. You think they are essential?—It is essential that dogs should be used.

7068. Have you read Professor Starling's evidence on that point?—I have read it, but I have not looked at it recently.

7069. However, speaking from your own experience, do you think that it would be possible to dispense with them?—No, I do not.

7070. Would you give us your reasons?—Because other animals are too small. For many of the experiments guinea-pigs, rabbits, and cats are too small, and other animals of the same size, such as sheep, goats, and pigs are too expensive.

7071. Is there any importance in the fact that the dog is carnivorous?—I think there is. I think that in experiments, for example, on the composition of chyle or digestive experiments they are very important.

7072. We have had some evidence given by two or three witnesses who are against experiments on living animals, to the effect that an animal differs so materially from a human being that only false deductions can be drawn from experiments on animals; do you agree with that view?—That is quite untrue.

7073. There are differences, of course?—Yes.

7074. But allowing for those differences, can an experimenter get trustworthy results?—Yes. If I may give an example, if you give nitrate of amyl to a man it quickens his pulse very greatly; if you give it to a rabbit it very often does not alter the pulse rate at all; the reason of that is that the pulse rate in a rabbit is very quick to start with. If you give nitrite of amyl to a dog it has the same action as upon man—it quickens the pulse rate; but if before you give it to a dog you cut the vagi in the neck so that the pulse rate becames as quick as it is in the rabbit it does not quicken it any more than it does in the rabbit.

7075. The engine is running at its maximum speed?—That is just it, but when you get those two experiments together you can at once see what is the action of nitrite of amyl.

7076. (*Dr. Gaskell.*) You would not draw any limit as to how low you might go down in the animal kingdom and still get advantage?—No, I do not know where you could draw the limit, because we are now going lower and lower in the animal scale and still get an advantage.

7077. (*Sir Mackenzie Chalmers.*) You yourself have not used curare since 1875, I understand?—To tell the truth I do not recollect when I last used curare.

7078. Would any detriment to science result if curare was prohibited, or if further restrictions were put upon its use?—I do not know. For my own part I should not be inclined to allow the use of curare as an anæsthetic.

7079. The Act prohibits that?—I think that is quite right, but if an animal is anæsthetised I do not see why you should not use curare. It will not increase any pain—it will do the animal no harm, and it might possibly be of service in keeping the animal quiet. There are certain cases which one can conceive where the employment of curare might be very useful. For example, if you wish to find out the effect of any stimulation of a sensory nerve upon the circulation, apart from any movement induced by a motor nerve, you might find the employment of curare advantageous, so that I think I should certainly not prohibit its use.

7080. (*Dr. Gaskell.*) Would it not also be of use in the case of peripheral stimulation of nerves to find out the question of circulation of blood in the muscles?—Yes.

7081. That could not be done without curare?—No.

7082. (*Sir Mackenzie Chalmers.*) Taking your evidence generally, am I correct in saying that you think that the continuation of experiments on living animals is indissolubly bound up with advance in medical science?—Yes.

7083. I take it broadly that the distinction between observation and experiment is that in the case of an experiment you deal with conditions artificially produced, and in the case of observation you have to wait until Nature or some external cause produces those conditions?—Yes.

7084. And you may have to wait an indefinite time?—Yes.

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S., 24 April 1907.

7085. And you cannot isolate the factors?—That is the chief difficulty.

7086. For instance, in the testing of drugs by observation, you only get an empirical result?—Yes.

7087. And by experiment you get a scientific result?—Yes.

7088. You get at the cause, and you can isolate the various conditions one by one?—Yes, that is so.

7089. Now, coming to particular cases, two witnesses have referred to your own experiments, which I may call baking and freezing experiments, and you have explained the baking experiments. May I take it that the temperature to which the animal was exposed was in no case higher than that to which an ordinary human being goes in a Turkish bath?—Certainly, in no case.

7090. So that if the animal had not been anæsthetised no more pain or discomfort would have been experienced by that animal than if it had been put into a Turkish bath?—Surely.

7091. (*Dr. Gaskell.*) So far as temperature goes?—Yes.

7092. (*Sir Mackenzie Chalmers.*) I am speaking only of temperature. You did not give us any evidence about what one of the witnesses before us called the freezing experiments. I suppose you have tried the effect of reducing the temperature?—Yes.

7093. Do you happen to know to what extent the temperature was reduced?—In one of the experiments on the action of aconite, the pigeon was shivering as if it was very cold, but its temperature was 103.1.

7094. What was the temperature of the air to which it was exposed?—The temperature of the air was 100 Fahrenheit.

7095. That is practically ordinary blood temperature?—Yes; but then it was low for a pigeon.

7096. Did you in any of these experiments bring down the temperature below freezing?—I do not think so, so far as I can recollect.

7097. May I put it in this way: As regards low temperature, so far as you remember, did you expose any animal to any temperature to which it would not be subject in its wild state on a winter's night?—Certainly not, and then, of course, every precaution was taken that there should be no local irritation, either from excess of heat or from excess of cold applied, for example from a portion of the cold metal touching the skin. The boxes were always padded, either with cotton wool or with paper, so as to prevent any local irritation.

7098. Have you followed lately the experiments on snake poisoning with Calmette and Fraser's sera?—Yes.

7099. Have any improvements been made lately?—I do not think so. I do not think that Calmette has made any further improvements.

7100. They were tested some years ago by Dr. Douglas Cuningham, I think?—I think they were, but I had forgotten it.

7102. You have not followed out that particular branch lately?—No.

7102. How many years is it since you first made experiments on animals?—I first experimented in 1865.

7103. And you have practically held a licence up to quite recent years, have you not?—No, my work has been very much interrupted. Practically I have not done a great deal of work myself since about 1877, because at that time I found that my practice was getting in the way, and the only plan of doing experiments was to get an assistant whom I paid, who should carry out the experiments which I devised.

7104. But still you have been connected with people who have been experimenting on living animals for many years?—Yes.

7105. Have you ever known of any case of inhumanity or want of consideration for causeless pain; I am speaking of England, of course?—No; in England certainly not, and I do not remember any case abroad, because, as I said before, most of my experiments were done in Professor Ludwig's laboratory in Leipsic, and he was always most careful of the feelings of the animals that were experimented upon.

7106. In those that he saw?—He would not allow anything that approached to cruelty in his laboratory. So careful was he, that whenever a frog was killed by cutting off the head, he would not allow the student to throw away the head; he said, you must destroy the brain, because you do not know whether that brain may not have the power of sensation still.

7107. Have you seen a very convenient presentation of the case against vivisection drawn up by Surgeon-General Sir James Thornton?—No, I do not think I have seen it.

7108. He has collected his statements in alphabetical order?—No, I have not seen it.

7109. And on some of these statements you yourself have given evidence. May I put to you some of his statements and ask you for your comments as to how far you agree with them or not?—Surely.

7110. Speaking of abdominal surgery, he says: "Abdominal surgery has been seriously retarded by experiments on living animals. The following statement was made by Sir Frederick Treves in his 'Address on Some Rudiments of Intestinal Surgery,' delivered before the Midland Medical Society at Birmingham, and reported in the 'British Medical Journal,' November 5th, 1898:—'Many years ago I carried out on the Continent sundry operations upon the intestines of dogs, but such are the differences between the human and canine bowel, that when I came to operate upon man I found I was much hampered by my new experience, that I had everything to unlearn, and that my experiments had done little but unfit me to deal with the human intestine.'" How far do you agree with that statement?—Sir Frederick Treves has, of course, more knowledge of his own condition than anyone else; but I believe that he has since modified his statements so as to show that the impression that it appears to have conveyed to Surgeon-General Thornton is incorrect.

7111. Apart from Sir Frederick Treves' opinion, what is your opinion?—My opinion is definitely that but for experiments on animals abdominal surgery would not now exist.

7112. The next thing he discusses is anthrax. I do not know whether you have paid special attention to that or not?—No, not special attention.

7113. I will only take those heads which I think seem to refer to yourself. Another head is the Calabar bean. He says there: "The most conflicting testimony is given by different physiologists as to the action of Calabar bean upon men and animals, and it appears that no positive conclusion can be reached as to its action upon the vagi nerves. Dr. Harley declares that it does not affect the arteries when applied locally. Dr. Fraser contradicts this, and says he has demonstrated that the local application of the drug produces dilation of the arteries." That is brought forward to show that experiments on Calabar bean have been futile. What is your comment upon that?—Practically, Calabar bean is not used for its action upon the vessels, but it is used for its action upon the eye, and that was discovered first of all by Fraser in his experiments upon animals.

7114. This passage therefore, you think, is a little irrelevant to the question whether experiments on living animals with Calabar bean have been useful or not?—I think so. With regard to the vagi, that is a question of dose. With a small dose you will get a stimulation of the vagi; but if you give an enormous dose you get paralysis.

7115. You get different results, I suppose, even if you take common salt?—Yes, with a little common salt and water you get an appetite; with a lot of salt and water you get the exact opposite.

7116. Then he goes on to chloral hydrate. He says: "Experimenters contradict each other about the physiological action of this drug in the most bewildering manner. Chloral hydrate has not sustained in the case of human beings the conclusion derived from its use upon animals; indeed, it is a question whether it has not proved an evil rather than a benefit in treating disease. Of its injurious effects on the human mind there is now no doubt, though it was at first recommended expressly on the ground that it had no such evil mental results. The error naturally arose from experiments being made with it on animals with no mental constitution analogous to that of man." What is your comment upon that?—There, again, it is a

question of dose and a question of amount. What was made out in animals was the question of the soporific action, and, to a certain extent, an analgesic action upon animals. Both of these are applicable to human beings. The effect upon the mental power of human beings is that if you give chloral hydrate in proper doses it will produce quiet sleep and comfortable sleep, followed by no bad results, for a long time together; but when people get into the habit of drugging themselves with chloral hydrate they may bring on mental aberration, and I have even seen a patient who was confined in a lunatic asylum because no one knew she was in the habit of drugging herself with chloral hydrate until she was confined, when the whole thing came out, and then she became cured. But there has been no fallacy introduced at all by experiments upon animals. The experiments upon animals were restricted to finding out certain points about chloral hydrate which were definitely ascertained by the experiments on these living animals. You cannot give an animal chloral hydrate for months and months together to find out the effects upon its mental condition.

7117. The next subject that Sir James Thornton goes on to deal with is chloroform. I think you have made experiments on chloroform yourself in Hyderabad and elsewhere?—Yes, very many.

7118-9. After pointing out that chloroform was not discovered by reason of experiments on animals, Sir James Thornton proceeds to say: "No experiments were ever made in connection with the discovery of the anæsthetic properties of chloroform." Do you agree with that statement?—So far, it is right in that the anæsthetic action of chloroform was discovered by experimentation upon man, unless the story be true that it was accidentally discovered in the voluntary experiment of a dog upon itself. The story is—I do not know whether it is true or not—that a chemist had got hold of some of this new stuff, which he put in a little jar in a corner of his shop; and one day a lady came in with a little lapdog. The little lapdog went smelling all round, and smelt at this jar, when it fell over insensible; and that was what started Professor Simpson on his experiment. But the definite experiments in regard to its anæsthetic action were really made by Professor Simpson upon himself and on Dr. Matthews Duncan and one or two others.

7120. But, as regards the safest way of keeping it and the best way of administering it, has that been investigated by experiments upon animals?—It has been investigated by experiments on animals, but a good deal of it has been made out upon man. The number of experiments upon man, as compared with the number of experiments upon animals, is simply enormous.

7121. (*Colonel Lockwood.*) Then Sir James Thornton is right in that?—Yes; I think he is so far right. I should not contradict that.

7122. (*Sir Mackenzie Chalmers.*) Then he says generally, under the heading of "Cruelty of Vivisection": "It is unnecessary to enlarge upon this point, as the cruelty of experiments on living animals is self-evident, and is admitted by most of the experimenters themselves." What is your comment upon that?—It is not true; it is not admitted. The cruelty of experiments upon living animals is not great, and it is not admitted. There is very little pain inflicted in experiments upon living animals, and I should say that there is no cruelty at all—that any pain that may be inflicted is either inadvertently inflicted, and there is very little, if any, of it; or it is because they think that by, possibly, putting an animal to a certain amount of inconvenience (I would hardly say pain), they may save pain to their patients.

7123. The next point he deals with is diabetes. Is that a question you deal with—I will read you what he says upon it—or would you rather not express an opinion?—I am quite willing to answer any question about it.

7124. "It has been claimed," he says, "that the experiments of Claude Bernard, Schiff, Pavy, and others have thrown much light upon this disease, but, however interesting from a scientific point of view, these investigations have not enabled physicians to cure the disease. As Dr. Althans observes, glycosuria which is experimentally induced is not diabetes such as we observe it clinically, but only a passing physiological storm, which is certain to disappear in a short time, and which, moreover, reproduces only one of the symptoms of diabetes. The experiments referred to are therefore of no value as regards the cure of this disease." What is your comment upon that?—It is simply this—that the experiments of Claude Bernard and others have taught us a great deal about the nature of diabetes; that they have not taught us all yet, and because we have not learnt everything it is simply useless to decry the utility of the things we have learnt. It seems to me that in any physiological or vital problem we deal with our materials as a man does with a bridge. A man goes on building the piers of a bridge on both sides for a length of time, a couple of years perhaps; there is no sort of good. Nobody can pass across the stream or the valley until at length they are so far completed that the keystone is put in, and then over the whole thing they go. But unless the piers are built first you will never get the keystone in. With diabetes we have been getting the piers built up, and before long I think we shall get the keystone in; but I am quite willing to grant that we do not know anything like the whole pathology of diabetes yet.

7125. As the result of experiments, can you alleviate diabetes in any way?—Yes, very greatly indeed; because before Bernard's experiments we did not in the least know that the amount of sugar that was passing was due to the conversion of starch into sugar, whereas now we know that, and we limit the diet of the diabetic to proteid foods, cutting off the starches and the sugar as far as possible, and giving them only proteid and fatty foods. In this way we can lessen his sufferings and can prolong his life.

7126. The patient remains in a chronic state, instead of the disease becoming acute; is that it?—Not always. There are many cases where there is sugar in the urine and where, if the sugar were allowed to remain, the patient might perhaps pass on to a condition of true diabetes. These cases we now term glycosuria only, and by simply putting them upon a proper dietary for a length of time we stop the sugar. We can then gradually give them back the farinaceous food, and even the sugar, without any sugar appearing in the urine; in fact, we cure them permanently, although if the disease were allowed to go on it would probably have turned into chronic diabetes.

7127. His next statement relates to digestion, and Sir James says: "The most valuable contributions in this direction are those of Dr. William Roberts, of Manchester, and the experiments necessary for them were made in laboratory vessels, not on animals at all. In fact, all experiments upon digestion can be made outside the living body with greater accuracy and ease than in it." What is your comment on that?—My comment on that is that we can experiment with the juices (pepsin, pancreatin, and so on) outside the body, but until we had learned by experiments upon living animals the relationship of these with different organs, we could not have carried on these experiments, which can now be carried on in the laboratory—that all the foundation has been laid by experiments on living animals, and now other experiments can be made without any further use of animals.

7128. He then goes on to deal with diphtheria and antitoxins. I do not know whether you have any special opinion on that. We have had evidence from Sir Douglas Powell about it?—My own experience is that the diphtheria antitoxin is an extraordinarily valuable thing, that it practically robs diphtheria of much of its terror. Before, diphtheria was a frightful disease. You got a sudden call to see a child affected by it, but you could do little or nothing for it, and the child died; whereas, with the antitoxin you simply find that the membrane sometimes will melt away like butter.

7129. At any rate it is a powerful remedy, not a cure?—It is a powerful remedy, and a most useful one.

7130. Referring to the antitoxin Sir James Thornton says: "It may cause paralysis, kidney disease, heart mischief, and other disorders, and in some instances, when used on healthy persons as a prophylactic, it has caused sudden death like a dose of deadly poison." What is your comment upon that?—I should think in relation to the alteration in the circulation, to which he refers, as well as the paralysis are much more likely due to the diphtheria disease than to the antitoxin—to the toxin, and not the antitoxin. So far as regards these cases of sudden death, I do not know anything about them; but what one does know is that

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.

24 April 1907.

many people are very liable to faint from very comparatively slight operations.

7131. Like vaccination?—Such as vaccination. I was told that on board the troop boats taking young, healthy officers out to South Africa, the number of men who fainted on simply being inoculated for enteric fever was extraordinary, and sometimes in certain peculiarly nervous people, instead of getting simple syncope they get fatal syncope.

7132. You would attribute the deaths then rather to what I may call sudden syncope than to the toxic action of the serum?—Yes.

7133. But you do not know the cases to which he refers?—No, but it is quite evident that it was not due to the serum, because the toxin does not act instantaneously like that.

7134. You think that that observation of his is unfounded, or made under a misapprehension?—People may have died from the disease, but it is not from the serum.

7135. You disagree with his statement that "when used on healthy persons as a prophylactic, it has caused sudden death, like a dose of deadly poison"?—Yes, it may be so, but I should say that the operation of inoculation has caused it, but not the serum.

7136. Then the next heading he takes is drugs generally, and Sir James says: "It has been asserted that 'nearly all the facts definitely known regarding the action of remedies have been gained by experiments on animals.' A direct contradiction is the best answer to this preposterous claim, experiments with drugs and animals having not only been futile, but also misleading. Dr. Rutherford was misled by his experiments on animals so far as to declare, contrary to universal experience, that calomel diminished the secretion of bile. The most contradictory opinions have been put forward as to the action of drugs on animals, showing that the experiments were quite useless, and only calculated to cause error and confusion"?—Well, if a man says that the moon is made of green cheese it is very hard to convince him that it is not, if a man makes a statement like that.

7137. You would say that that is too general a statement for you to deal with?—Yes, it is too general a statement to deal with. That is a statement made in pure absolute ignorance.

7138. Then I will pass over various cases which I think more or less surgical, and his next heading is myxedema. He says: "It has been stated that a cure for this disease was discovered through vivisection; but this is not the case. Dr. Murray, of Newcastle, discovered, though not by vivisection, that an injection of the extract of the thyroid gland of a sheep into myxedemic patients would improve their health and avert death, but the treatment must be persisted in regularly, or relapses occur." Do you agree with that or did Dr. Murray experiment on living animals in fact?—It is said that a partial truth is worse than a lie. Sir James Thornton is perfectly correct about Dr. Murray, but he should go a step or two further back, and ask how Dr. Murray came to use this treatment. If he does that he will find that the whole treatment that Dr. Murray adopted was founded upon experiments on animals.

7139. He then speaks of nitrite of amyl. I think you have also mentioned that?—Yes.

7140. He says: "The claim that nitrite of amyl was discovered and brought into use through vivisection is quite unfounded. This substance was discovered in 1844 by the French chemist Balard, and was introduced to the medical profession in 1865 by the late Sir B. W. Richardson for the relief of angina pectoris, the action and properties of the drug having been by that time well ascertained. Some years later certain experiments on animals were performed by Mr. Gamgee with this drug, but nothing was discovered that was not known before." What is your comment upon that passage?—First of all he has got his dates wrong. It was not introduced as a remedy for angina pectoris by Sir B. W. Richardson in 1865. It was recommended by him in 1864 for syncope and for tetanus, but he never did come to discover its use in angina pectoris. The experiments upon animals performed by Gamgee were performed in 1866, and showed the action of the drug in lowering the blood pressure, a fact which had not been ascertained before; and it was this fact which led to the use of the drug in angina pectoris.

7141. As you have explained to us in an answer in a previous part of your evidence in the case of a St. Bartholomew's patient?—Yes.

7142. There is another remedy, is there not—nitroglycerin?—Yes. I made the physiological experiments with that in 1876, and I published them in the St. Bartholomew's Hospital Reports. I am unfortunately very liable to headache, and when I experimented with it it gave me such awful headaches that I hesitated to test it upon my patients, because I was afraid of giving them headaches such as I had got, but in the meantime a few months after I had done my experiments Dr. Murrell used it.

7143. Your experiments were on animals?—Yes. He introduced it, and it has proved perfectly satisfactory. Mr. Tate and I showed that the action was just the same as that of nitrite of amyl.

7144. But you give it in a different way, do you not, in which it is more convenient to give it?—Yes. It acts rather more slowly, and its action is more prolonged.

7145. How is it given?—It is usually given in little tablets mixed with chocolate.

7146. I need not trouble you perhaps with the details, as you have answered generally?—Here it is (*handing in a book*).

7147. Then Sir James goes on, I think, to deal with Pasteur's antirabic inoculations, and he contests the value of those inoculations. Have you any practical experience of the Pasteur treatment?—Yes. I was a member of the Commission sent across to investigate the utility of Pasteur's treatment; I went over perfectly convinced that Pasteur was wrong.

7148. What was the date of that Commission?—About 1884 or 1885, but I came away perfectly convinced that Pasteur was right, and there is no doubt whatever, I think, in the mind of any unprejudiced person that Pasteur's treatment has produced a complete revolution in the treatment of hydrophobia. Hydrophobia was a most frightful disease. Just before I went over I was a member of a Committee of the British Medical Association to investigate hydrophobia, and I went throughout all the country examining cases; and the cases I saw were simply heartbreaking. As the result of it I got inoculated, and had to burn it out.

7149. Your own finger got inoculated?—Yes, unfortunately, with rabid poison when making a post-mortem examination.

7150. What treatment did you pursue yourself?—Caustic potash; there was nothing else. I took a stick of caustic potash and rubbed it in, and scraped it out and rubbed it in again.

7151. Did you go through Pasteur's treatment?—No; it was before Pasteur's treatment; that was the only treatment available at the time, but it does not improve the fingers.

7152. You satisfied yourself on that Commission that Pasteur's treatment saves life?—Absolutely.

7153. Have you followed recently the results of the Pasteur treatment in the new laboratory at Kasauli in India?—No.

7154. A laboratory has been established there to enable Pasteur's treatment to be applied in India, where there is a great deal of rabies?—Yes.

7155. You cannot give us any information upon that?—No.

7156. Who could?—That laboratory is under Hankin, is it not?

7157. I do not know whom it is under. I did not know where we could get any information?—You could easily get it from the India Office. Sir Benjamin Franklin could possibly provide you wth all you want.

7158. Then Sir James Thornton speaks very strongly in favour of Buisson's treatment by baths; was that in any way investigated by your Commission?—No, we did not deal with that.

7159. Have you any opinion about it?—It is a very old treatment, but, like other old treatments, it was quite unsatisfactory.

7160. You think experience has proved it to be unsatisfactory?—Yes. It was tried, of course, without any definite results.

7161. Has it been tried with reference to animals as well as man?—I do not think so, but I cannot be sure.

But you could get information about it, I daresay, from Dr. C. J. Martin, of the Lister Institute.

7162. Then the next heading is Poison Tests, and Sir James says: "Poisons act in such different ways on men and animals that deductions from experiments on the latter are fallacious and misleading. Rabbits can eat belladonna with impunity; dogs, aloes; apes, strychnin; and goats, hemlock; while birds in general are little affected by morphia. Even in human beings the effects of certain poisons are greatly modified by race. All this tends to show how vain a thing it is to expect to find out remedies for our own diseases by experiments upon animals, which are not constituted as we are, and which frequently find their food in things which would be fatal to mankind." How far do you agree with that general statement?—A number of the instances are quite correct. The general conclusion is quite erroneous. For example, rabbits eat belladonna with impunity, just in the same way (as I mentioned before) as, if you cut the vagi in a rabbit, you find no change in the pulse rate. If you cut the vagi in a dog you see its pulse rate going up at once. If you give a dog belladonna, at once you will get the pulse rate go up too; the reason being that in a rabbit the vagi act ordinarily hardly at all, whereas in the dog they are constantly acting. When you paralyse the vagi in a rabbit with belladonna there is no difference. If you paralyse the vagi in a dog you get a great difference at once, just as you get a difference at once in a dog's pulse rate when you cut its vagi. When he says that birds in general are little affected by morphia, they are very much affected by morphia, but in a different way. For example, pigeons are not much affected apparently by morphia in the way of its causing drowsiness, but it acts upon them as an antipyretic—it lowers their temperature as much as if you put them in a very cold place—so that they are affected, though in a somewhat different way.

7163. But the point of Sir James Thornton's criticism is that these substances act so differently on animals and man that you can draw no true inference from one to the other. What is your comment upon that?—The same may be said of the action of the drugs upon different men. A dose of aloes, which he says may be swallowed by dogs with impunity, may be swallowed by certain men with perfect impunity; and yet we know that in the great majority of human beings aloes will act as a purgative, notwithstanding the failure to do so in those individuals. The same with opium. Sir Robert Christison used to tell us of a particular family who were not affected by opium. Sir William Hamilton, the Scottish metaphysician, would swallow an ounce of laudanum with perfect impunity—it had no action at all upon him; but it was not that he was an opium-eater or accustomed to it.

7164. It was a pure idiosyncrasy?—Yes; and it was inherited by his eldest son. But still the majority of people are affected by laudanum; so that what holds good in all he says in regard to animals applies in the same degree to man: that we can only tell from observation on man the effect of drugs upon the majority; that we will find exceptions just as we find them in animals.

7165. And by experiments is it possible to make the necessary allowance?—Yes.

7166. (*Chairman.*) I do not quite see how that is in the instance you gave. If pigeons generally are made cold by taking morphia, and it has not that effect on humanity, does not that show that you cannot experiment on pigeons with regard to the effect of morphia as an anæsthetic or soporific?—No, because you see I have dealt with that very question in this paper on the effect of heat and cold, upon the action of aconite on pigeons.

7167. I am assuming that what you say about it is quite correct as a fact. But after knowing what the effect of it was on pigeons, you would not experiment on pigeons with morphia with a view to obtaining information for the treatment of man, would you?—Yes, certainly; and for this reason, that there are differences in men. There are certain people who are called gouty who tend to pass out their nitrogenous waste in the form of urea or uric acid. Other people tend to pass out their nitrogenous waste in the form of urea, and what Dr. Cash and I were very anxious to find out was whether we could trace any relationship between the action of morphin on pigeons, which, like other birds, passed their nitrogenous waste out in the form of urea or uric acid and gouty people; because there are certain classes of people on whom morphia or opium does not act as a satisfactory soporific; instead of causing sleep it causes excitement. We thought that very likely by experimenting on animals we should find out whether this bears any relationship to the mode of excretion of nitrogenous waste. We find, for example, that morphia will not act upon pigeons and other animals that excrete uric acid, and we thought perhaps that we might find by going to work at the bedside, that men who excrete uric acid would not be satisfactory subjects for morphin. We were not able to continue the experiments, but that was the line of them; and if they are continued on those lines I think we shall get very valuable information indeed in regard to the action of drugs on account of the very variations in their action upon different animals, which will enable us to isolate the different factors which determine the kind of action of a drug upon man, by finding out one factor or another on the different animals upon which we experiment.

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.
24 April 1907.

7168. (*Sir Mackenzie Chalmers.*) The next heading is, perhaps, too wide a one to discuss at this time; it is "Preventive Inoculation," and that raises too wide a question to go into?—It is not one to which I have paid particular attention.

7169. Then Sir James Thornton discusses Snake Venom, and states that Sir Joseph Fayrer in 1904 pointed out the effect of permanganate of potash?—Yes, but it was before then; it was long before that. He mentioned it first of all in his book, "Thanatophidia of India."

7170. I presume it is, at any rate, from experiments on animals that you can test the proper mode of administering a drug like permanganate of potash?—Yes.

7171. You can only test the best way of dealing with snake bite by inoculating an animal efficiently, and then noting the different conditions under which the drug operates successfully or unsuccessfully?—Yes, that is so.

7172. There is an enormous loss of animal life as well as of human life in India through snake bite, as you know?—I believe they are beginning to use those little lancets for animals as well.

7173. That is an improvement that has been made in recent years as the mode of administering the antidote?—Yes.

7174. Then he takes the heading "Rheumatism," and he says: "Lactic acid is found in the bodies of rheumatic patients, and its injection into animals produces rheumatic symptoms; but this information has not resulted in the discovery of any means of preventing or curing the disease." That I imagine is true?—I think that is true.

7175. Have you anything to say for those experiments? Are they likely to be useful or useless?—I do not know that they are any use as yet, although one does not know what the result may be. As I said before, in all those things we have to accumulate a good deal of information before we get any practical application.

7176. I have only one more point to put to you. Under the heading "Temperature" Sir James Thornton says: "No alteration in the treatment of fever has resulted from the experiments of Claude Bernard on raising the temperature of animals till death occurred. These experiments therefore were totally useless." What is your comment upon that?—That is not so. I think perhaps the best comment I can make, if you will allow me, is to give you a case that I once saw. When I was a student, a man with pneumonia came into the hospital in Edinburgh, and was dying. Professor Bennett, who was a clinical physician, was very much disgusted because this was going to spoil his average. He said that he had had over a hundred cases of acute pneumonia, and he had never once lost a case. However, this man was really dying; he was moribund, so Professor Bennett gave a grunt and passed on. A Swiss named Skolberg, who was visiting the clinique, asked what did Professor Bennett think about the man. "He is going to die." "May I treat him?" "Yes, you can do what you like with him." So Skolberg pulled off all the bedclothes; he got a sheet, dipped it in a tub of water, and wrapped it round the man, pulled it off again in five minutes, and then repeated the dose. I went away, but about half an hour or three-quarters of an hour afterwards I returned, expecting to find the bed empty. To my

Sir T. L. Brunton, M.D., F.R.C.P., F.R.S.
21 April 1907.

astonishment, I found the man lying there, apparently perfectly well and sleeping comfortably. That man was dying of hyperpyrexia; but that was just before the introduction of the clinical thermometer, and we did not know what he was dying of. It was a bit of pure empiricism. But the experiments on animal temperature now allow any student to know what is happening and to know the time when he is to apply the cold douche and so to save the lives, not of one, but of many. What was then a mere accident is now the routine practice.

7177. You have explained the reason by experiment?—Yes.

7178. And therefore you can apply the treatment intelligently rather than empirically?—Yes. Of course, the effect of the treatment is 1,800 years old. Musa, the physician of Augustus, saved the Emperor's life by cold baths, but, not knowing how to apply them, he killed the Emperor's nephew, the next patient he had to treat.

7179. (*Dr. Gaskell.*) I just want to ask you one question with reference to a question put to you by Sir William Church. We have been told that there is a difficulty about anæsthetising, dogs especially, because the anæsthetic is so liable to cause death, and that the margin between death and complete anæsthesia is so small that it is impossible to keep the animal under complete anæsthesia. Do you consider that dogs are more liable than other animals to have stoppage of the heart through vagus action in consequence of the administration of chloroform?—No, I do not think that they are.

7180. You do not think that dangerous symptoms come in in the case of dogs early in the anæsthesia?—No, I do not think so. I think that there is very little danger with dogs, if you are watching what you are doing. All the time we were in Hyderabad the only fatalities we had were when somebody was not attending to his work. All the others went quite smoothly; we had no difficulty whatever.

7181. Is it not frequently the case that when you give chloroform to dogs you have what you speak of as vagus pulse?—Yes; but I do not think that that makes any difference. It does not kill the dog in the least. And you get it in man too.

7182. You do not think, then, that there is any more difficulty in keeping a dog under chloroform or that it is any more liable to death than in the case of cats or other animals?—Certainly not; and less than in the case of rabbits. I should put the dog upon very nearly the same plane as a man; I should say that the difficulties with a dog and man are just about the same. But with a rabbit, if you do not do it rightly, you do get death. There are two entirely different ways of chloroforming rabbits. One is to do it very gently, with a bell jar, and allowing the chloroform to increase very gradually until the animal becomes insensible. The other way is simply to cram the chloroform on to a cloth and stick it over the rabbit's nose and keep it there until it goes under. Either way is quite safe; but a combination of the two is unsafe. If you begin gently, and then cram it on, and then do it gently again, it does not do.

7183. You have had experience of chloroform given to a vast number of dogs?—Yes.

7184. And you have entirely convinced yourself that they have been under anæsthesia?—Yes, entirely.

7185. And complete anæsthesia?—Complete anæsthesia; as complete as any patient could possibly be under on the operating table.

SEVENTEENTH DAY.

Wednesday, 1st May 1907.

PRESENT:

The Right Hon. the Viscount SELBY (*Chairman*).

Col. the Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. MACFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.D.

Captain C. BIGHAM, C.M.G. (*Secretary*).

Miss L. LIND-AF-HAGEBY, called in; and Examined.

Miss L. Lind-af-Hageby.
1 May 1907.

7186. (*Chairman.*) You are a native of Sweden, I believe?—Yes.

7187. And you resided there and were educated there, until you came over to England for the purposes of attending lectures?—Yes; and I have been living in England a great deal. I was at school in England, but I have been living here since 1902—practically residing here.

7188. Before you left Sweden, I understand that you took a great interest in this question of vivisection?—I did, a very great interest since 1900.

7189. And you took an active part in the agitation against vivisection?—I have taken an active part in the agitation for some seven years.

7190. Since 1900, you mean?—Yes.

7191. Did you receive any medical education in Sweden?—No, I did not. The medical education I received I received here; but it was never our intention to take up the study of medicine—it was simply to study physiology.

7192. For the purpose of assisting your action on the question of vivisection?—Yes.

7193. You were a confirmed anti-vivisectionist when you came over to England?—We were.

7194. You and Miss Schartau were joint authors of a book called "Shambles of Science"?—Yes. Although we were confirmed anti-vivisectionists in a way, we were quite open to conviction, and were anxious to find out what vivisection really was and to get more knowledge. We found that we had not sufficient knowledge to fight against it as we were doing, and it was out of a desire to get more knowledge and get more thoroughly acquainted with it that we decided to take up the study of physiology.

7195. You had had no previous experience of physiology or of attending lectures?—No, but it was a visit to the Pasteur Institute in Paris that made us interested in the whole question; it was the things we saw there which made us really care for the question.

7196. The principal thing we wish to have your evidence upon is the cases that you refer to in your book, in which it is alleged or suggested that there were breaches of the law and cruelty; and perhaps it would be more convenient to take them just in the order in which you refer to them in the book?—May I be allowed to read a statement which I have prepared? It is very much in connection with the book and very much in connection with my whole point of view.

7197. I am afraid we should have things twice over

Miss L. Lind-af-Hageby.

1 May 1907.

in that case. It would result in our hearing a good deal twice over, because it would be necessary to ask you as to the precise facts you there speak to on each of those experiments. I propose now to go through them, and if, when I have done, that there is anything you wish to add, you will have an opportunity?—In my statement I have prepared certain information in connection with those experiments which have been already brought before the Commission; but before that I have some evidence which to me it is absolutely necessary to give in connection with "Shambles of Science," and in connection with statements that have been made already before the Commission; and I therefore shall be very grateful if I may be allowed to read it, as to me it is very closely connected.

7198. We find that when witnesses read statements they very often have not got present to their minds what the object of this Inquiry is so much as what their own views are, and we find that those statements very often go into matters which are not really relevant to our Inquiry?—I am afraid that my evidence will not be of the same use if I am not allowed to read my statement, as other witnesses have been allowed; for instance, Professor Starling, Mrs. Cook, and others have been allowed to make statements; and I have prepared my statement very carefully. All my statement is composed of corroborative facts which to me are absolutely essential if I am to present my defence of "Shambles of Science" from the point of view of the accusations which have been made; and I am afraid if I am not allowed to present it in this way, I must beg leave to withdraw as a witness. I do not feel justified, in the interests of the cause that I represent, in defending my book in a way that would not do justice to the cause.

7199. You must remember that it is not your book that is on trial here; it is the experiments that you speak to. You say that it is a statement of facts that you wish to read?—I wish specially to speak to those facts in immediate connection with my book; but also I understand, if the Commission wish to hear my observations, that I have the same right to speak on the general question as Mrs. Cook has done, and Dr. Arabella Kenealy, and other witnesses who have come from the anti-vivisection side.

7200. Yes; I am not disputing that you are at liberty to speak on every possible relevant question?—I do not intend to do that. I have limited myself to physiology. I should infinitely prefer to be allowed to read a statement, as other witnesses have done.

7201. You have sent us a *précis* of your evidence?—Yes. May I be allowed to say that I have endeavoured to give in my *précis* the very same points as I have in my statement.

7202. I was going to follow your *précis*, in which you begin by stating that you wish to give evidence especially in connection with your book "Shambles of Science" and passages contained therein, which the Commission have already dealt with, and the experiments on the so-called "brown dog" and other facts bearing upon the basis and progress of the anti-vivisection cause?—Yes, but if you read the next point in my *précis*, there are certain things I wish to bring out before I come to that.

7203. I was going to follow on with that?—I have a short statement on the ethical side of the question, and I thought I should be allowed to read that first.

7204. Very well; will you give us that?—The "Shambles of Science" was inspired by moral indignation, and written as a protest against the cruelties of vivisection, the callousness of vivisectors, and the demoralising effect of vivisectional demonstrations before students. Before I proceed to lay before the Commission facts which corroborate the accusations made in the book, I wish to plead the priority and the ultimate persistence of the moral objection and revolt against experiments upon living animals. There can be no doubt that the vivisection of human beings would at present be of the utmost scientific value to the same section of scientists who claim the right to vivisect animals, but the majority of vivisectors shrink from expressing such desires, though there are exceptions. We have advanced so far in our moral conceptions that a general clamour for human beings for vivisectional purposes would meet with disapproval and resentment. The question of utility or uselessness is here rightly deemed to be immaterial in comparison with the moral issue, and in the same way a further moral development will prohibit the vivisection of animals. The history of the evolution of morals affords repeated proofs of such moral victories. The use of instruments of torture for the purpose of extracting especially coveted information has been abandoned in most civilised countries. Religious as well as scientific torture of human beings is condemned as immoral. There can be no doubt that, were the arguments of the vivisector to be considered a safe moral guidance in other walks of life, the artist and the sculptor might crucify in order to further realism in their art, and the writer of drama might order the infliction of pain and suffering on the helpless for a similar purpose. Few would deny that humanity is as much in need of art as of science, and yet divorced from morality they both become scourges instead of blessings. From the purely physical point of view it might be advantageous to kill off a few thousands of our incurable lunatics, imbecile children, incorrigible paupers, worst criminals. But we refrain from acting in accordance with such a view because we are restrained by a moral consciousness which was non-existent in our savage state. Moral evolution has forced us to include the sub-human races in the circle of our compassion and our sympathy. Kindness to animals, gradually passing into a conscious acknowledgment of their rights and our duties towards them, is the last and finest product of our developing altruism. From the moral point of view the elimination of the unfit means the elimination of the cruel and the selfish. In the light of progressive morals anti-vivisection is not an isolated fad or the expression of uncurbed sentiment—it is part of a great whole, of a humanitarianism which includes every sentient creature in its protective embrace, and which condemns every form of cruelty to man or beast. The abolition of vivisection, then, becomes an unavoidable moral necessity of the future; for the growth of sympathy and the demand for justice cannot permanently be stopped by any appeals to our cowardly fears or to purely egotistic considerations.

I now come to my evidence in immediate connection with the "Shambles of Science," and everything I am going to say now is closely bound up with the book. I have brought some copies in case anybody would like them.

7205. Now you are going to speak with reference to the experiments which you saw and your description of them?—Yes. I am going to try to give my own experience of vivisectional demonstrations and vivisectional anæsthesia, as well as certain evidence in corroboration of that experience.

7206. Do you mean other experiments which are not mentioned in your book?—No, I shall not speak to any experiments except those I have seen—not generally, of course. I have some corroboration, of course. I am afraid I do not quite understand the question.

7207. I thought from what you said that you were proposing to give evidence of breaches of the law in experiments in operating rooms and laboratories on other occasions than those referred to in your book?—No.

7208. This surely would be more convenient to take by question and answer. We are now coming to the first of them?—Yes, I am now coming, if I am allowed, to what experiments are "absolutely necessary," if I may read a very short statement. I have not taken it from the point of view of going through the whole book chapter by chapter; I should never think the Commission would have time to listen to it if I were to give lectures on each chapter; and I have simply taken certain facts.

7209. What we want to get at is the facts. When you speak of "painless experiments" you give what took place on a certain occasion in a lecture room with reference to a frog?—Yes.

7210. What really took place is what we want to know?—Yes.

7211. Because you know very well that some of the physiologists differ from you?—Yes, I do.

7212. And some who were present on the occasion differ from you and give different accounts?—Yes.

7213. Then in order to get at the facts we must pursue the ordinary method of doing it—that is, to ascertain what your statement of the precise facts is to which the other witnesses speak?—If the Commission would perhaps find it possible to follow the *précis*, the next point is that the "Shambles of Science" throws light upon the manner in which the provision of the Act of 1876, that only experiments which are "absolutely necessary for the due instruction of the persons to whom such lectures are given" is interpreted. That

Miss L. Lind-af-Hageby.

May 1907.

is a point which runs through the whole book rather than one single chapter.

7214. You are speaking now of experiments for instruction and demonstration?—Yes, and I am very anxious to bring out a point here, that point being that the Act of 1876 demands that only experiments which are absolutely necessary shall be performed in illustration of lectures; the principle underlying this restriction evidently being that too much vivisectional demonstration before students would have a demoralising effect—at least it must be some notion like that which underlies that Section of the Act. I wish to bring out now that our experience as recorded in the "Shambles of Science" shows that a great many experiments are performed before students which cannot be justified as being "absolutely necessary for the due instruction of the persons" (those are the words of the Act) "to whom such lectures are given, with a view to their acquiring physiological knowledge or knowledge which will be useful to them for saving or prolonging life or alleviating suffering." As an instance, I have mentioned in my *précis* the injection of diseased spinal cord matter taken from a lunatic into a dog. I have mentioned that as an instance of an experiment that cannot very well be said to be absolutely necessary.

7215. That is on page 75 of the book?—That is the page.

7216. You want to prove from what you saw then that it was unnecessary?—Yes. I refer to that experiment especially as one that cannot be said to be one that was absolutely necessary; and my contention is that all the experiments are more or less unnecessary. May I proceed on this point?

7217. If you will tell us what you find in this chapter which supports your argument?—In this chapter my argument is supported by the fact that this experiment has no therapeutic value whatever; further, that it was not absolutely necessary to demonstrate it from the physiological point of view. I do not know whether I am to mention the names of the physiologists who performed these operations.

7218. Certainly?—I do not wish to mention their names with any desire to libel them. The Commission wish me to mention their names?

7219. Certainly?—I want then to bring out that Professor Halliburton, who conducted this demonstration, in his "Handbook of Physiology" refers to the test for cholin; and he says the cholin may be tested in two ways—by a purely chemical test and by a physiological test; but—these are not his words, but it is my opinion—as there are the two tests it was not absolutely necessary to choose the test of injecting it into a live animal; he might just as well have chosen the purely chemical test. Further, as I said, the experiment is of no therapeutic value whatever, and Professor Halliburton himself does not seem to assign great value to this experiment, for he says in his Handbook, on page 177: "It is possible that such tests may be of diagnostic value in the distinction between organic and so-called functional diseases of the nervous system."

7220. Was Professor Halliburton one of those engaged in this operation?—Professor Halliburton was the lecturer upon that occasion; and my contention here would be that when the lecturer himself does not know or is very doubtful as to whether there is any diagnostic value, even diagnostic value, in such an experiment, that particular experiment should not have been one which is tried before students. Further, I wish to state that the choice of what is absolutely necessary seems to depend upon the individual taste of the physiologists who are lecturing and demonstrating. Thus Dr. Bayliss, during the Bayliss *v.* Coleridge trial in 1903, referred to his particular experiment upon which the action was based as one that was "absolutely necessary"; whilst Professor Gotch, of Oxford, during the trial said that that particular experiment was not included amongst those which he showed to his students. That shows, in my opinion, that the choice of what is "absolutely necessary" depends on the individual taste of each vivisector, and that one might ask why there is not a certain curriculum, a certain number of experiments which are agreed upon as being "absolutely necessary" and performed before students, but that there is unlimited freedom in the choice of that which is "absolutely necessary."

7221. Are there any other of the experiments which you refer to in this book which bear upon that point of demonstrations?—My point—from my point of view—of course I do not expect physiologists to share it—is that none of those experiments can really be said to have been absolutely necessary for the due instruction of students.

7222. You select this one as what you consider a strong instance?—I select it as a strong instance; that is all. May I now go on to my second point in connection with the book?

7223. Yes?—The descriptions given in the book in connection with the subject of vivisectional anæsthesia and the lack of humaneness on the part of lecturers and demonstrators who, whilst they are anxious to impart knowledge to their pupils of the theories of experimental physiology, neglect altogether to inculcate any ideas of mercy or carefulness in the treatment of the animals, are corroborated by the tone and instructions which characterise most modern textbooks and handbooks on physiology, theoretical and practical. Vivisectors have lately laid claim to humaneness in the execution of their pursuits, and have disdainfully repudiated connection with the old vivisectors, who were cruel, or foreign vivisectors, who may be cruel now. Thus there was a letter in the "Times" of March 12th, 1902, by Sir Victor Horsley, in which he referred to foreign vivisectors in these words. He was speaking of a representative of the anti-vivisection agitation, saying that he "confuses what may be done in Germany in the direction of operating on animals without anæsthetics with what is actually done in the United Kingdom under anæsthetics, and terms it all vivisection." There are many other instances of similar statements, which I do not think I need read to the Commission. But the veracity of their claims is disproved by their own teachings. If everything were done to teach students the moral obligation of being merciful to the victims of scientific research these textbooks and handbooks would show some trace of it. They would contain special and serious warnings against the infliction of pain, and special and detailed instructions as to the care of animals from the humane point of view, both during the operative and the observational periods of experiment. The following well-known books contain no such warning or instructions. (I have brought all these books with me to-day.) "Directions for Class Work in Practical Physiology," by E. A. Schäfer, 1901; "Exercises in Practical Physiology," by Aug. D. Waller, Part II., 1905; "Essentials of Experimental Physiology, for the Use of Students," by T. G. Brodie, 1899; "Practical Physiology," by Beddard, Edkins, Hill, Macleod, and Pembrey, 1905; "Halliburton's Handbook of Physiology," 1905; "Elements of Human Physiology," by E. H. Starling, 1905; "Outlines of Practical Physiology," by William Stirling, 1902; "An Introduction to Physiology," by L. A. Hodgkinson Lack, 1905; "Essentials of Human Physiology," by D. Noël Paton, 1905; "Essentials of Physiology for Veterinary Students," by D. Noël Paton, 1905; "A Manual of Physiology," by G. N. Stewart, first edition 1895, fifth edition 1905; "Textbook of Physiology," edited by E. A. Schäfer (for advanced students), 1898. The following books are by four American professors of Physiology, but have English or Anglo-American publishers, and are widely known and studied in England:—"Textbook of Physiology," by W. S. Hall, 1900; "Handbook of Physiology for Students and Practitioners of Medicine," by Austin Flint, 1905; "A Textbook of Physiology for Medical Students and Physicians," by Will. S. Howell, 1905; "Laboratory Manual of Physiology," by Fred C. Busch, 1906. I have not said that directions as to the administration of anæsthetics are absent from all these books, but I wish to point out that, although some are less callous than others, on the whole they lack all signs of any dominating wish to attempt the humane teaching and practice of experimental physiology. I now come to my next point, and that is that incomplete anæsthesia is frequently advised in these textbooks for students. One of the most important lessons to be drawn from a study of these textbooks is the utter inadequacy and unreliability of vivisectional anæsthesia as a means of abolishing pain. "The sleep of anæsthesia is a pathological condition due to the action of a poison," says Professor Halliburton in his "Handbook of Physiology," and experience of vivisection as it is taught and as it is carried out shows that experiments frequently require partial or perfect freedom from that condition.

7224. From what condition?—From the condition of anæsthesia. Instead of warning students against cruelty, some textbooks deliberately advise light anæsthesia, and warn their readers against employing anæsthetics in a manner which would bring about deep anæsthesia.

7225. What was Professor Halliburton speaking in reference to in that passage?—Professor Halliburton was there merely speaking as a scientist, and not with any special reference to demonstrations. I simply quoted his words as being an authority, and saying that the sleep of anæsthesia is a pathological condition due to the action of a poison; and I brought it in here to show the likelihood of physiological experiments being frustrated and injured by anæsthesia.

7226. (*Colonel Lockwood.*) Have you got Professor Halliburton's book?—I have it here.

7227. (*Chairman.*) Would you just read the passage again?—"The sleep of anæsthesia is a pathological condition due to the action of a poison."

7228. (*Sir Mackenzie Chalmers.*) If you can give us the page we can see for ourselves?—I am afraid I have forgotten the page.

7229. (*Chairman.*) You only read part?—The rest was my own.

7230. What followed a little surprised me?—It was badly read by me. I have said that these physiological books for students, as I am going to show, frequently require perfect or partial freedom from that condition—the condition which Professor Halliburton refers to as a pathological one.

7231. We should like to see the passages, if necessary?—I have got all the passages marked.

7232. I do not want them read, but you will give us the references so that they may be examined, because so much depends upon the context?—In support of this I beg to draw the attention of the Commission to Professor Brodie's book "Essentials of Experimental Physiology for the use of Students." Professor Brodie was lecturer on physiology at the London School of Medicine at the time of my attendance there.

7233. (*Sir William Church.*) The London School of Medicine for Women?—The London School of Medicine for Women. In this book Professor Brodie expresses his preference for light anæsthesia and curare in the following terms, at page 176, dealing with stimulation of the sciatic nerve: "Often, too, struggling movements are produced, especially if the animal be only lightly under the anæsthetic, when with each convulsion the blood pressure rises considerably. The only completely satisfactory method of obtaining a pure pressor effect is to previously curarise the animal"; and at page 202, dealing with the superior laryngeal, he says: "We may stimulate this nerve in two ways. We may imitate the normal method by introducing into the larynx a curved probe whose end has been wrapped in cotton wool. In this instance, and, indeed, for all these nerve stimulations, the rabbit must not be too deeply under the anæsthetic."

7234. (*Chairman.*) Do you understand that to mean that he is advocating that the rabbit should still be sensible to pain?—I do not mean to suggest that Professor Brodie is advocating that, but I mean to suggest that vivisectional anæsthesia is exceedingly unreliable, as the deeper stages of surgical anæsthesia are not compatible with physiological research. On page 206, dealing with stimulation of the central end of the vagus, he says, "This result is much better obtained if the anæsthesia be not too deep." Professor Stewart's "Manual of Physiology" shows the usual fear of too deep anæsthesia, though the last edition is better in this respect than the first. In the practical exercises attached to the various chapters which give full directions for vivisectional work, students are advised only to give ether in addition to morphia or chloral "when necessary"; and on page 156 of the first edition, dealing with stimulation of the depressor nerve in the rabbit, we read: "Anæsthetise a rabbit with ½ gramme chloral hydrate, and, if necessary, with ether. In blood pressure experiments only small doses of chloral hydrate or chloroform can be given, as they affect the vasomotor centre." Dr. Waller gives a similar caution in his "Exercises in Practical Physiology" (Part II., pages 46 and 47).

7235. There, again, do you mean to suggest that in the doses he recommends he is recommending a dose which would not produce insensibility to pain?—I am not at the present moment dealing with doses.

7236. Well, quantities?—I am not at the present moment dealing with doses; in fact, I do not know that the doses are given in these cases.

7237. I am not speaking of this specific dose. But he says there should be a light anæsthesia?—Yes, I mean to suggest that all these (and there are one or two or more that I want to bring out on this point) imply the induction of an anæsthesia which from the humane point of view is unreliable because it is too light, and I am going to endeavour to prove by these facts that that is generally practised in physiological laboratories.

7238. That is the real point we know, whether it is generally practised; and this is really a little outside our inquiry, as to what doctors write in books and recommend. It is what is done that we are concerned with, because they may not be recommending it but saying that certain effects will not be produced under heavy anæsthesia?—I do not think it is outside your inquiry when in the "Shambles of Science" I have described what I have seen done. These are the theories which would be responsible for the doings I have seen. It is corroboration.

7239. We might have to go into the education of every doctor who performed an operation, at that rate. We are not so much concerned as to what doctors have written on the question, and what the effect of light or heavy anæsthesia would be upon animals, as upon what is done?—But if I were to come before the Commission and simply say I have seen this, and I have seen that, I have every reason to believe that the Commission naturally would not look upon me as an authority on the subject, but would probably take the opinions of physiologists, who hold entirely different opinions, as more valuable; but if, at the same time as I bring my own experience, I corroborate that experience by theories as they are put down in every current and modern text book, I consider that I strengthen my case considerably.

7240. (*Colonel Lockwood.*) You are arguing that the anæsthesia as recommended by the authorities you quote is so light as not to render the animal insensible to pain?—I mean that it is very possible that the animal may not be insensible to pain.

7241. (*Sir William Collins.*) Are you quoting from the handbooks of physiological laboratories?—I am quoting from handbooks all of which I have brought with me.

7242. (*Sir John MacFadyean.*) Would you admit that there is any point in the argument if the authors of these books tell us that when they said the anæsthesia was not to be too deep they never for a moment intended it to be so light that the animal was to be conscious?—I quite admit that the defenders of vivisection would say that, but my point is that vivisectional anæsthesia is unreliable, because the scientific requirements do not tally with the humane requirements, and because these scientists would always rather follow the scientific requirements than the humane ones.

7243. May I point out that the train of your argument really seems to involve a belief on your part that they intended to suggest that the anæsthesia should be so slight that the animals might be conscious; because it arose in connection with a question of cruelty?—My whole evidence is in connection with cruelty.

7244. So that you do wish us to believe that these authors deliberately intended to advise that in certain cases the anæsthesia should be so slight that the animal would probably be conscious?—I have never said that or suggested it. I have said that they advise light anæsthesia, and I have not suggested anything as to what their views are on the animal feeling pain or not; in fact, I think in most cases they hold no views on that subject when they write these books. But I mean to suggest from the anti-vivisectionist point of view that it is very likely that the animal is insufficiently and improperly anæsthetised, and therefore we anti-vivisectionists have a very strong reason to complain.

7245. (*Colonel Lockwood.*) Why do you say it is "very likely"?—Because I know, and I think everybody knows something, of the difficulties of anæsthetising generally, what a science it is, what an art it is; and from my experience of vivisectional anæsthesia I know how that is practised, too. And if the dominating idea is to have a light anæsthesia, the dominating idea cannot be to have profound anæsthesia; and we know that anæsthesia is always fluctuating between deep and

Miss L. Lind-af-Hageby.

1 May 1907.

light, and that therefore the tendency, the weight of balance would be towards the light, towards the return of consciousness, rather than towards the total and permanent abolition of consciousness.

7246. (*Chairman.*) It all depends upon whether those are really instructions which would be read by any medical student as instructions for the purpose of allowing animals to be too lightly anæsthetised, so that they still should feel pain—whether that is the intention?—May I read again Professor Brodie's words: "This result is much better obtained if the anæsthesia be not too deep." This book is written for students.

7247. "Is not too deep"; but yet it may have to be deep enough to prevent pain being felt by the animal?—Professor Brodie would no doubt say that; but the whole fight over this question is on the different points of view. There are different opinions, and I present one side of the case.

7248. But you are citing a book and suggesting that it has a certain meaning, and then you say that therefore it is advocating to a certain extent cruelty—it is encouraging cruelty?—No; I say that it may lead to cruelty.

7249. (*Dr. Gaskell.*) Do not you know that in this kind of experiment of which you have quoted there is a difference in the result according to the amount of anæsthetic given?—That is just what I am suggesting.

7250. That it is not a difference of pain; it is a difference in the pressor or depressor effect, and also in the action of the nerves on the vasomotor centres?—Yes?

7251. And if there was any pain, the experiment could not be carried out at all?—I do not think that is so. I shall bring further evidence to show that experiments can be carried out under pain. Dr. Waller gives a similar caution in his "Exercises in Practical Physiology" (Part II., pages 46 and 47) in these words: "Stimulation of the Central End of the Lingual nerve. The lingual nerve is ligatured near its entrance to the mouth, and so stimulated. Unless the animal is too deeply anæsthetised, salivation is accelerated"—in other words, that is another caution that too deep anæsthesia would interfere with the experiment. In Professor Halliburton's Handbook there is another caution in these words: "It is essential, when the experiment of stimulating the cortex of the brain is being performed, that the animal should be anæsthetised, otherwise voluntary or reflex actions will occur which mask those produced by stimulation. If, however, the animal is too deeply under the influence of a narcotic, the brain is inexcitable." This statement of Professor Halliburton is supported by many similar expressions in the literature of vivisection. Thus Dr. David Ferrier, in his book "The Functions of the Brain" (2nd edition, 1886) says, in speaking of electrical stimulation of the brain, at page 224: "That which will cause intense and indefinite action in an animal non-narcotised will excite only moderate and definite action in an animal sufficiently narcotised to abolish all sense of pain, and no effect at all on an animal deeply anæsthetised." And on page 232: "Deep narcosis, however, abolishes the excitability both of the grey matter and the subjacent medullary fibres, so that no reaction whatever occurs in the application of currents otherwise effective." On page 166 in Professor Busch's "Laboratory Manual of Physiology," dealing with the subject of excretion, students get the following advice: "Narcotise a rabbit, lightly, with morphin. Anæsthetise with ether just sufficiently to keep the animal quiet." There is no attempt to introduce any moral consideration into these words—"just sufficiently to keep the animal quiet."

7252. (*Chairman.*) Is that your observation?—That is my observation—but instructions are then given for the utilisation of this animal for a number of other experiments. The Commission do not probably want to hear about them, because this is an American book; but it has an English publisher and is very well known in England. I have only a few more remarks about it.

7253. I think you might confine your evidence to English books. You have read a number of passages, and the real question is, What is the fair meaning of those passages? I do not think you add anything by going to American books. We may take it that a great number of books do contain expressions such as you have quoted. The question is really what is the fair meaning of them?—My next point is that there are cases where even no anæsthesia is spoken of as a condition that is quite likely to occur to be necessary. It is certainly not only light anæsthesia that is advocated in these textbooks; sometimes they calmly describe the course of experimental results in unanæsthetised animals, or point out that better results are obtained if no anæsthetics are employed. The following instances illustrate this. From "A Manual of Physiology," by G. N. Stewart (5th edition, pages 137-138)——

7254. Is that a modern book?—All the books are modern. The 5th edition was published in 1906.

7255. By "modern" I really meant after the Act of 1876?—Yes, all my books, I should say, are within the last 10 years. He is dealing with the depressor nerve in the rabbit, and he says: "Excitation of its central end causes a marked fall of blood pressure, accompanied by, but not essentially due to, a distinct slowing of the heart. If the animal is not anæsthetised there may be signs of pain, and for this reason the depressor has sometimes been spoken of, somewhat loosely, as the sensory nerve of the heart."

7256. What do you suggest is the suggestion made to students there?—The suggestion made to students is that experiments have been performed on animals that are not anæsthetised. "If the animal is not anæsthetised there may be signs of pain" when the depressor is stimulated; and my suggestion here is that experiments on unanæsthetised animals productive of pain do not seem to be an impossibility to teaching vivisectors—nor do they withhold information.

7257. But do you really infer from that that Mr. Stewart is practically admitting that since the Act of 1876 licensed persons have performed these operations without anæsthetics?—I do not mean to infer anything more than what is said.

7258. But does it say that?—I do not think that writers on physiology have the Act of 1876 in front of their eyes when they are writing these textbooks for students. I think they are purely considering the scientific aspect of the matter.

7259. But when you are asking us to draw such strong inferences against a writer, is it not quite consistent that he is describing the result of observations that he has made when he has seen such operations performed in France or Germany?—I cannot possibly say what Professor Stewart meant to infer, but I shall come later on to similar statements by Professor Starling about the effect of pain, and I only quote them as being material to my side of the case; I cannot draw any inferences.

7260. I only suggest that if they only go so far as that, they do not seem to me to assist you at all?—I am afraid I must leave it to the Commission to draw inferences. I am not here to do that.

7261. (*Sir John MacFadyean.*) But you read this evidence to us with a special object, which is, to get us to draw certain conclusions?—Certainly.

7262. Do you wish us to conclude from it that the writers have actually performed, or that any other licensed person has performed painful experiments without anæsthetics?—I wish the Commission simply to draw the conclusion, first, that experiments are desirable under light anæsthesia, which I have already shown; and, secondly, that there are cases where no anæsthesia is scientifically preferable; and without committing myself to saying what was done here or there, or anywhere where I do not know, or suggesting anything personal or definite in connection with breaches of the Act. I only bring this scientific wish and scientific desire and scientific necessity before the Commission, and I must leave it to the Commission to draw their own inferences. Professor Flint says, in his "Handbook of Physiology for Students and Practitioners of Medicine," page 373: "If the abdomen of a dog, perfectly quiet and not under the influence of an anæsthetic, is opened, and a portion of the liver excised, rinsed in cold water and rapidly cut up into boiling water, the extract will show no reaction with Fehling's test for sugar." From the same book, page 374: "A notable experiment on the influence of the nervous system on the liver is the one in which artificial diabetes is produced by stimulation of the floor of the fourth ventricle (Bernard). The operation is not difficult. The instrument used is a delicate 'stilet' with a flat cutting extremity and a small projecting point about $\frac{1}{25}$ of an inch (one millimetre) long. In performing the operation on a rabbit, the head of the animal is firmly held in the left hand, and the skull is penetrated in the median line, just behind the superior occipital.

protuberance. This can easily be done by a few lateral movements of the instrument. Once within the cranium, the instrument is passed obliquely downward and forward, so as to cross an imaginary line drawn between the two auditory canals until its point reaches the basilar process of the occipital bone. The point then penetrates the medulla oblongata between the roots of the auditory nerves and the pneumogastrics, and its projection serves to protect the nervous centre from more serious injury from the cutting edge. The instrument is then carefully withdrawn and the operation is completed. This experiment is almost painless, and it is not desirable to administer an anæsthetic, as this in itself would disturb the glycogenic process."

7263. (*Dr. Gaskell.*) Would you mind mentioning to the Commission that Professor Flint is an American?—Professor Flint is an American, but this experiment is one that is frequently referred to in all textbooks on physiology, and I have here an English book describing the same experiment—it is "Recent Advances in Physiology and Bio-Chemistry," edited by Leonard Hill (page 340)*—which likewise describes those experiments, also without mentioning any anæsthetic.

7264. (*Chairman.*) What Professor Flint, I understand, said was that it was better to perform it without any anæsthetic?—Professor Flint distinctly says that anæsthetics must be avoided in experiments on the glycogenic function.

7265. Then it is very material to know that he was an American, because his book was written in America (and I suppose originally for Americans) where there is no vivisection law I understand in most of the States; therefore it is a very different case from that of England?—I wish to bring out, too, that an English book, "Recent Advances in Physiology and Bio-Chemistry," edited by Leonard Hill, describes the same experiment, also without mentioning the use of anæsthetics.

7266. But Professor Flint does mention the use of anæsthetics. Does the English author use the same phrase about anæsthetics?—No; he says nothing about it at all.

7267. But that is a most material difference?—I quite appreciate the difference, and I quite appreciate, too, why the English author says nothing about it.

7268. You think that by not mentioning the use of anæsthetics in a country where the law is that anæsthetics must be used, the author is implying that they ought not to be used?—I should think that as a scientist, as a physiologist, Dr. Hill knows quite well, what all physiologists know, that these particular experiments have to be performed without anæsthetics. I cannot form any opinion as to what he means by not saying anything about them.

7269. Are you citing this for the purpose of bringing home to our minds the action taken by those who advise the students in England?—Yes.

7270. I want to know whether you are reading that passage to show us that they refrain from advocating the use of anæsthetics, and therefore encourage illegal operations by such a passage as you have just read to us in an English author's book?

7271. (*Sir Mackenzie Chalmers.*) You know that that experiment would be illegal in England?—Yes. I am not at present dealing at all with how the law is carried out or administered.

7272. (*Chairman.*) It is the interpretation of what the author means that we are dealing with; we have to interpret his meaning, and one wants a great deal more than that. Do you mean to suggest that he is inculcating the illegal performance of operations in his book?

7273. (*Sir William Collins.*) Does Dr. Hill say that glycogenic experiments can be successfully performed in England without anæsthetics?—No, he does not say that, but he would know as a physiologist that it would be impossible from a purely physiological point of view. I now come to "Practical Physiology," by Beddard, Edkins, Hill, etc.

7274. (*Sir Mackenzie Chalmers.*) What Dr. Hill is that?—The same Dr. Leonard Hill. On page 156 we read, "The gastric secretion is obtained by making an incision in the stomach, as in Figure 138, and then reflecting and suturing the mucous membrane of the stomach so as to make a separate secreting sac which is still in muscular and nervous continuity with the rest of the stomach. The mouth of the sac is sewn to the opening in the abdominal wall. The vagus is exposed and divided." I must say in fairness, that there is a note in Mr. Beddard's book saying "This experiment cannot be demonstrated." That note, I should think, evidently refers to the English law; but these are the words: "Three days later the peripheral end of the vagus is excited in the unanæsthetised animal, and the juice collected. Anæsthesia or operative procedures easily inhibit the gastric secretion."

7275. (*Chairman.*) Is Dr. Leonard Hill an Englishman or an American?—An Englishman. This is an English book, "Practical Physiology." This experiment is one typical of the methods of the Russian physiologist, Professor J. P. Pawlow, Director of the Physiological Department of the Institute for Experimental Medicine, St. Petersburg.

7276. (*Colonel Lockwood.*) But it does not refer to experiments done in England?—Yes, I am coming to that. Professor Pawlow has been much quoted lately by physiologists as a vivisector who is able to work under "perfect physiological conditions"—that is, no pain and no anæsthesia. Professor Starling has described those conditions as "an ideal" which has been attained by Pawlow; and in his admiration for these methods he used the following words in his evidence (Question 4119): "You get an animal and you alter its anatomy in some way or other so as to make some process accessible to simple observation, so that you can see what goes on without interfering in any way with the animal's comfort or with the animal's normal condition." In the Harveian oration for 1902, Dr. Ferrier refers to these methods as "novel and luminous." And there are many expressions of admiration for his methods in the literature of physiology. But a direct reference to Professor Pawlow's lectures published in England under the title "The Work of the Digestive Glands," shows that his methods are far from "ideal" or perfect from the physiological point of view, and that even those vivisectional methods speedily become pathological instead of physiological, and that disease and suffering are by no means absent. On page 183 Professor Pawlow says:—"I had by no means the intention at first to set up conditions of disease; I operated solely for physiological purposes, and kept my animals alive for months or years. How many and how profound pathological processes have under these circumstances come into existence before my eyes! I have seen in connection with a disturbance of the functions of the liver an enormous ascites develop, at another time an ascending paralysis of the central nervous system, or, again, a general lacerability of the blood-vessels, and so on." On page 171 he speaks of a dog which got an ulcer in the artificial gastric cul-de-sac, which gave rise to violent bleeding and produced a secondary peritonitis. And in describing pancreatic fistulæ he tells us (on page 7) that only one in every four or five dogs will be found which tolerates the operation without any nursing, meaning thereby that it is a difficult operation, which takes a great deal of nursing, or the animal will die. I suppose that is what is referred to. I have brought this before the Commission, although it may seem irrelevant, because Professor Starling, in quoting Pawlow's experiments, has at the same time brought forward a plea for more experiments in the future under Certificate B, that is, the certicate which allows the animal to recover from the anæsthesia and to be kept alive, and under which several operations are at present performed legally on one and the same animal. But Pawlow shows clearly himself that he has not attained any ideal conditions by any means. He uses the very words here in contradistinction to Professor Starling. Professor Pawlow himself says: "Our solution of the problem"—that is of these fistulæ—"is evidently by no means an ideal one" (page 8), and he tells in this book which I have brought with me how these fistulæ—pancreatic and other fistulæ—frequently produce corrosion and various skin troubles, which must give a great deal of discomfort and pain to animals. He tells a story of one of the dogs in his laboratory, and I am relating this because these are the vivisectional methods of the

1 May 1907.

future. Professor Starling has referred to them repeatedly before the Commission. Professor Pawlow tells the story of a dog in which a pancreatic fistula had been established, one of those animals to which Professor Starling refers as just having had the anatomy altered a little, so that the animal is "quite happy," says Professor Starling; there is no inconvenience. I do not remember his exact words, but he repeats several times that the animals are "quite happy." Professor Pawlow says that one morning he found that one of these dogs had torn down part of the wall in the laboratory, to which it was chained, and he found the animal was lying on the pulverised wall, evidently to try and take away the pain and the suffering that came from the corrosion which was caused by the constant trickling of the pancreatic juice; and the next morning he found that this dog had again, in its efforts to save itself, torn down another part of the wall to which it had been chained. And then Professor Pawlow found that he could devise certain means of taking away part of its pain and discomfort by allowing the animal to lie on sand. But I wish specially to point out that these experiments are by no means free from pain or discomfort.

7277. (*Chairman.*) Are you giving us the account now of an experiment which can be done in England without anæsthetics, or, at least, of a case in which a dog may be kept alive after the experiment?—I am quoting this to show one instance of experiments which can be done, and are done, in England now under Certificate B, and which have been specially brought out by Professor Starling as the "ideal" experiments of the future.

7278. But what you have been telling us happened in Russia?—Yes, because Professor Pawlow has been referred to.

7279. (*Sir John MacFadyean.*) Was that an exceptional case that you read, or was it the normal result of the experiments?—Professor Pawlow in several pages here relates the great difficulties he has had in making the state of these animals as normal as possible, but he by no means pretends that they are in a normal state.

7280. But would this be an average case or a special one?—This is a passage on page 6 in Professor Pawlow's book. It says: "In a very short time the abdominal wall becomes macerated by the escaping juice, and in places even fairly large bleeding patches appear. These continuously irritate the animal, and prevent the collection of pure juice by means of the funnel." Then, further on, he says that even now, when he has succeeded by many new methods, and after much trouble in preventing this corrosion and maceration of the skin, he seeks better methods, because the continual escaping of the pancreatic juice puts the animals in an abnormal condition, which interferes with their general state of health.

7281. But perhaps it was the exceptional painless cases that Professor Starling had in his mind when he spoke about the ideal condition. How do you know that he referred to the bad cases?—I wish specially to point out that Pawlow himself, after having quoted all his difficulties and improvements, says: "Our conditions are yet far from ideal."

7282. (*Sir Mackenzie Chalmers.*) These were early experiments?—No; these are the latest. I have the book here.

7283. What is the date?—1902. A new edition is being prepared, and, I hear, will be out in three weeks.

7284. (*Sir John MacFadyean.*) But Pawlow lectured in this country within the last two years, did he not?—I believe he lectured here last autumn.

7285. May he not have described the improved methods in those lectures?—I think he described the latest improvements, as he terms them, there; but it is after describing his improvements that he says of his methods: "Our conditions are yet far from ideal."

7286. But it was prior to 1902?—I do not think there has been any change since 1902, but I am not competent to answer that. I was not present at the lectures.

7287. You wish us to infer that Professor Starling's remark about Professor Pawlow's operations being ideal refers to those which you have quoted from the book?—Yes; that is what I understand.

7288. That is what you offer to us?—Yes, that is it; and may I also say that those conditions which are desired to be ideal, but which are not in reality ideal, are exposed by another scientist—Paulesco, of Bucharest—who has written in the "Journal de Physiologie et de Pathologie générale," Paris (January, 1906), that he, too, has found that the establishment of biliary fistulæ leads to many abnormal conditions in animals which interfere with and frustrate the experiments. That anæsthetics interfere with the results of certain experiments is pretty generally acknowledged. That all physiological experiments are disturbed by the use of anæsthetics is freely admitted by the school of Pawlow. It is true that this school adds a theoretical and aspirational condemnation of pain, too; but in practice it is shown that pain is considered a lesser evil, and whenever there is a real conflict between moral and scientific claims, the vivisector chooses adherence to the claims of his science.

7289. (*Chairman.*) That is yours—you are not quoting?—That is my own.

7290. But, when you say that, what you are saying is that you apply it to English vivisectors. I suppose when you say the vivisector you mean the English vivisector?—I apply it to all vivisectors, including English.

7291. Then do you mean that the English vivisector, when he can get a better result with pain, defies the law?—Yes; I assume that. And I have a right to assume it at the present moment, because Professor Starling has said before this Commission that were there no such things as anæsthetics he would yet admire the man who performed experiments without anæsthetics—that is to say, the man who tortured animals for the sake of science.

7292. That is quite a different thing?—No; that is the same thing, I believe.

7293. That is quite a different thing from saying that he disobeys the law?—I only bring that forward in support of what I have just said—that if there is a real conflict between moral and scientific claims, the vivisector would choose adherence to the scientific claims.

7294. That is to say, that he would disregard the law, and perform an operation which caused pain because he got a better result?—I am not at present suggesting that anybody breaks the law.

7295. (*Sir John MacFadyean.*) Is there ever such a conflict in your opinion as you suggest there?—There is sometimes such a conflict as I have shown, and on the Continent no secret is made of such a conflict.

7296. Then you do mean to suggest to us that English vivisectors do break the law when that conflict arises?—Am I obliged to say again that I have not come here to suggest that British physiologists break the law.

7297. (*Chairman.*) But you use an argument which has no force whatever unless you are suggesting that?—I have come here to bring evidence of the existence of pain even in England.

7298. The sooner we come to that the better pleased I shall be. What we want is not suggestions that by a certain interpretation of a passage in a book such operations are encouraged, but real facts to show that they are actually performed?—I believe I am coming to that too, if I am allowed to proceed.

7299. The sooner we get to that the better?—With vivisectors and the defenders of vivisection cruelty is generally interpreted as the unnecessary infliction of pain and suffering, whilst in their opinion the supposed necessities of science at once justify the infliction of pain and suffering. This touches the very root of the unreliability of vivisectional anæsthesia. Foreign textbooks show great frankness in connection with the priority of scientific considerations to moral ones. For instance, Professor Robert Tigerstedt, a renowned physiologist, Professor at the University of Helsingfors, Finland, writes in his "Textbook of Human Physiology"—a book which is the standard textbook of German students, and which has now been translated into English, in 1906 (page 5): "Only if the purpose of the experiment makes it necessary is the operation performed on unanæsthetised animals"; and he adds: "Furthermore, it is many times of advantage in the experiment to suppress the voluntary movements of the animal, and this is done by administering the American arrow poison curare." A digression from textbooks into the records of experiments given by vivisectors in their journals and writings shows, if possible, still more conclusively their dislike of anæs-

thetics. A typical instance is afforded by a paper on "The Pathology of Asthma," by T. G. Brodie and W. C. Dixon, reprinted in "Collected Papers from the Research Laboratories of the Royal College of Physicians, London, and the Royal College of Surgeons, England" (edited by Brodie), Paper 19, Part I., 1903: "A considerable difficulty we met in all our early experiments, and which we only learnt to explain after much trouble, was due to the action of the anæsthetic. A large number of our early experiments gave negative results, which we ultimately found to be caused by the use of chloroform or ether as the anæsthetic. These, we found, paralysed the nerve endings in the bronchial muscles, and we only succeeded in obtaining constant results on vagal stimulation when their use was reduced to a minimum. We therefore adopted the practice of anæsthetising the animal with the smallest quantity of chloroform and then destroying the medulla and brain. No anæsthetic was then required." And further: "Thus slight reflex constrictions have been described as following excitations of the sciatic, superior laryngeal, central end of the vagus, the cornea and the nasal mucous membrane, but the tracings given in support of these statements are far from satisfactory. When working upon anæsthetised animals our attempts to produce these reflexes were almost entirely negative. It therefore became necessary to avoid the use of an anæsthetic altogether, or only to administer it for a very short time. As it was also necessary to keep the medulla uninjured, we worked upon decerebrate animals; but the conditions were still far from ideal, for the decerebration involves a rather lengthy operation under anæsthesia, and the injury produced in the majority of cases appears to set up a constant inhibitory effect upon the medullary centres. When working in this way we therefore decerebrated the animal and then kept it for some three or four hours before proceeding with the experiment, in order to allow ample time for recovery from the anæsthetic. But even under these conditions the results obtained have not proved as successful as we had hoped, and while giving the reflex effects we have at present succeeded in recording, we feel that there are still many undecided points to be worked out before we can understand the normal working of these centres." I have quoted that to show the difficulty that the physiologist meets with when he endeavours to employ anæsthetics, and how anæsthetics interfere with experiments.

7300. That is to say, that carrying out the law presents certain difficulties to physiologists. That is what they say?—Yes. In a book entitled "The Physiology and Pathology of the Cerebral Circulation," published in 1896, by Leonard Hill, M.B., who says he has opened "scores of living animals," there are clear indications that chloroform and ether are distasteful to the vivisector. The method of the experiments was the following: "A cannula was placed in the central end of the carotid artery. A second long cannula was passed down the external jugular vein, and on same side into the right auricle. The torcular heriphili was trephined, and a third cannula was screwed into the hole thus made. The cannula in the carotid artery was placed in connection with a mercurial manometer" (pp. 40 and 41). "My object," says Mr. Hill, "has been to make the method of research complete by simultaneously recording the arterial pressure, the general venous pressure, the intra-cranial pressure, the cerebral venous pressure." On page 40 we read: "The animals employed for this research were in most cases dogs. Morphia was the anæsthetic generally used; but the results have been controlled by the use of other anæsthetics. In no single case has morphia been found to obscure results, while ether and chloroform frequently do so." And on pages 58 and 59 we read: "Administration of chloroform produces a fall of arterial pressure and a rise in general venous pressure. . . . Ether produces a slighter fall of arterial pressure and a slight rise of pressure in the right auricle. . . . Morphia produces no peculiar effect on the cerebral or general circulation. . . . Thus morphia is far the best anæsthetic for researches of this nature. . . . the vaso-motor mechanism is in no way damaged by morphia, as it is by ether and chloroform." Sensory nerves were stimulated. We learn that: "Stimulation of any sensory nerve causes a rise of general arterial pressure and intra-cranial or cerebral venous pressure passively follows the rise." Curare was used, absinth, brain extract, and strychnine injected.

7300a. Is the object of reading that, to suggest that morphia is not an anæsthetic?—That brings me to my next point in connection with vivisectional anæsthesia and the "Shambles of Science," *i.e.*, that the use of morphia as an anæsthetic for vivisectional operations, especially when combined with curare, constitutes cruelty, and that such use of morphia is illegal under the present Act, as morphia is not, in the words of the Act, an "anæsthetic of sufficient power to prevent the animal feeling pain." Even in experiments before students morphia is used. I have seen severe experiments performed under morphia, for instance one described in the "Shambles of Science," under the title "An experiment that is not supposed to be useful." This experiment, which involved opening the chest of a dog widely, removing the ribs, setting up artificial respiration, enclosing part of one of the lungs in an oncomotor, and stimulations of various kinds, was, according to the lecturer himself (Dr. Brodie), performed under morphia. Other severe experiments described in the book were, in the words of the lecturers, performed under "morphia, and scarcely any anæsthetic at all," and under "morphia and a little chloroform."

Miss L. Lind-af-Hageby, 1 May 1907

7301. (*Colonel Lockwood.*) Where is that described?—In the "Shambles of Science."

7302. (*Sir Mackenzie Chalmers.*) Are these the lectures that you attended?—These are the lectures described in the "Shambles of Science."

7303. Did you see this experiment?—Yes, I did.

7304. (*Colonel Lockwood.*) Under what head is it described?—The experiment that was performed, in the words of the lecturer, "under morphia," is described on page 55 of the first edition.

7305. (*Sir John MacFadyean.*) Was the animal curarised?—Nothing was said about that.

7306. Is that the experiment of which you say in the "Shambles of Science" that "we can be almost certain the dog has been also curarised"—that occurs on page 60?—Yes, that is the experiment.

7307. A minute ago you said that nothing was said about its being curarised?—I said that nothing was said about it.

7308-9. But you think it is almost certain that it was?—What we thought at the time was that it was certain it was curarised. I have already given instances of the vivisectors' preference for morphia and their dislike of anæsthetics. It is only natural that they should attempt to prove that morphia has the power of abolishing pain in vivisected animals. During the trial of Bayliss *v.* Coleridge, Mr. Bayliss said on the second day that morphia is an effective anæsthetic. I do not think I need go into the many statements to that effect that have been made. But these attempts to prove that morphia is an anæsthetic are futile. Vivisectors can have no greater authority than their own Claude Bernard, whose special work on the action of anæsthetics and narcotics is universally known and quoted, and whose name at the present moment appears in almost every textbook, and whose illustrations of vivisectional operations are reproduced in English textbooks. Claude Bernard quite appreciated the utility of morphia from the vivisector's point of view, though he was honest enough to acknowledge its utter uselessness as an effective anæsthetic for vivisected animals. These are his words: "The animal still remains sensitive, a touch on the cornea induces the closing of the eyelids, but he is quite still, and lends himself without a movement to the most delicate operation. . . . He feels the pain, but has lost the idea of self-defence."

7310. (*Chairman.*) Do you suggest that the great majority of physiologists consider that morphia is not an anæsthetic?—I have not formed an opinion as to whether the majority or the minority do or do not; but I can bring forward a great amount of evidence of those who do not consider it to be an anæsthetic.

7311. When you used the expression about vivisectors, you have no better authority. There are a great many authorities who differ, as you know?—But Claude Bernard is very much appreciated, if one reads Sir Michael Foster's "Life of Claude Bernard," how he looks upon him as a father, and asks to be allowed to look upon the physiologists of France as his brethren.

Miss L. Lind-af-Hageby.

1 May 1907.

7312. We have heard a good deal of Claude Bernard since we have been sitting here?—I am coming to modern physiologists, if I may, in a moment.

7313. (*Sir William Church.*) Would you be good enough to tell us whether that statement, which we have had frequently before us, and which we have just had from you, by Claude Bernard, was spoken of morphia generally, or of a particular quantity of morphia in relation to an animal?

7314. (*Sir Mackenzie Chalmers.*) Have you the quotation there?—I have the quotation; but I do not think I have got the exact dose of opium that he refers to. I shall be pleased to send it, because I have the exact reference at home.

7315. (*Sir William Church.*) Will you please give us the exact reference to this passage of Claude Bernard?—I will.

7316. You are not yourself aware whether he made that statement of morphia in any quantities?—He made it about the action of opium on animals generally. These are his words: "The animal still remains sensitive, a touch on the cornea induces the closing of the eyelids, but he is quite still, and lends himself without a movement to the most delicate operation. . . . he feels the pain, but has lost the idea of self-defence." That is taken from Bernard's "Leçons de Physiologie Opératoire," page 155. Prominent veterinary surgeons who, above all, should have experience in this matter, deny that morphia is an efficient pain-destroyer. Among them I may mention Mr. Sewell, who has said that, in his opinion, morphia is not an anæsthetic for a dog in any sense. And Professor Hobday, who, I feel sure, is the best authority on animal anæsthesia which I can quote ——

7317. (*Chairman.*) You are going a little too far in stating what witnesses said at the trial. If they are alive they can be brought here to give the evidence?—Then I will leave out the trial. I now refer to Professor Hobday, and I am very anxious to bring this before the Commission, because Professor Starling said that Professor Hobday is coming to give evidence; and Professor Starling evidently thinks that Professor Hobday will give evidence in illustration of the general ideas in connection with vivisectional anæsthesia prevalent among vivisectors; but I do not think that Professor Hobday will give evidence of that kind, for in his book, "Surgical Diseases of the Dog and Cat," published last year, there is an important chapter on the art of giving anæsthetics to dogs and cats. In contradistinction to Mr. Leonard Hill, and many other vivisectors, he considers chloroform the ideal anæsthetic to choose for the average adult dog. Instead of supporting the vivisectors' contention, that morphia is an anæsthetic for dogs, he says that, "compared with man, the dog is extraordinarily insusceptible to morphia" (page 46). He also says on pages 45 and 46 that "It (morphia) is classed as a narcotic rather than as an anæsthetic; and although it certainly deadens pain for minor operations, it does not do away with it altogether, as is the case with chloroform and ether. It is distinctly a useful aid in that the dazed, stupid condition in which the patient is put, renders it more tractable and easily managed. Professor Cushny has appeared before the Commission, and, in answering questions 5150 and 5270, has said that morphia is an effective anæsthetic for dogs, and that a large dose of this drug acts as an anæsthetic. These statements are of special interest, because in his "Text Book of Pharmacology and Therapeutics or the Action of Drugs in Health and Disease" (the fourth edition, 1906), Professor Cushny expresses entirely different opinions—opinions which make his statements before the Commission strangely contradictory, or which show that Professor Cushny holds one kind of theories when he speaks as a scientific pharmacologist, and another kind when he speaks as an ardent defender of the doings of vivisectors. On page 208 of this book, he says of the action of morphia on dogs: "The sensation of pain seems to be much lessened, but not entirely abolished, and reflex movements are difficult to elicit. After larger quantities an exaggerated sensibility to external stimulation seems present, for the animal starts convulsively at loud sounds and on pinching, but when left undisturbed lies in profound sleep."

7318. Do you suggest that Professor Cushny there is offering an opinion that the animal was feeling pain?—My position is this: I had prepared this statement of Professor Cushny's in my evidence which I was to have given before the Commission when I was coming in March, as very strong and weighty evidence in favour of my view that morphia is not an effective anæsthetic in dogs. To my great surprise, on reading Professor Cushny's evidence before this Commission, I found that he entirely contradicted what he had said in his own textbook, where he says that larger quantities in the dog produce an exaggerated sensibility, and also that pain seems to be lessened, but not entirely abolished.

7319. (*Sir John MacFadyean.*) Are these not doses which are still non-poisonous?—I do not think that is inferred. He says that larger quantities produce an exaggerated sensibility.

7320. Is it possible, I suggest, that they are still non-poisonous?—That argument cannot be used here, because Professor Cushny says that larger quantities produce an exaggerated sensibility—the more you give the more exaggerated sensibility to external stimulation seems to be present.

7321. You think that follows?—I think it follows. I have the book here. He says at page 208: "The sensation of pain seems to be much lessened, but not entirely abolished, and reflex movements are difficult to elicit. After larger quantities an exaggerated sensibility to external stimulation seems present, for the animal starts convulsively at loud sounds and on pinching, but when left undisturbed lies in profound sleep."

7322. (*Sir William Church.*) But do you wish us to infer from what you have read and stated of morphia or opium that it is impossible, first of all, to stupefy a dog so that it cannot feel pain; and, secondly that it will not die afterwards from the effects of opium?—I think morphia is as little an anæsthetic for dogs as it is for human beings; and I am entirely supported there by Professor Hobday, who does not consider morphia in any way an anæsthetic.

7323. I wish you would give me an answer, please. Do you wish the Commission to take evidence from you that morphia, if given in large quantities, will not produce complete anæsthesia?—Yes.

7324. I mean in quantities that are fatal?—Yes.

7325. That is your statement, that it will not produce anæsthesia?—What I wish the Commission simply to take as my evidence is that I do not consider morphia to be an anæsthetic at all.

7326. You say that you do not consider it; but do you state that in your opinion an animal cannot be made perfectly unconscious with morphia, so deeply unconscious that it will not continue to live after a certain time?—I suppose you can poison it?

7327. Do you deny that you can do it in man?—I suppose you can poison a man to death with morphia, as you can poison a dog to death with morphia, I am not denying that, but at present I am speaking of the anæsthetic properties of morphia, and I say that it has none.

7328. Do you mean that a man, when unconscious from morphia, feels pain?—No, I do not mean that.

7329. Do you mean that when an animal is unconscious from morphia it feels pain?—There is a very great difference between an anæsthetic and a narcotic. If morphia were an anæsthetic it would be included in the numerous textbooks on anæsthesia.

7330. Never mind about the textbooks. I wish simply to get your opinion before the Commission. Do you think that when a man is under the complete influence of a sufficiently poisonous dose of morphia or opium he feels pain?—That case is somewhat apart from my case here. I must still maintain that I am speaking of morphia as an anæsthetic, not as a poison.

7331. (*Chairman.*) How long may a person or a dog live after it has received a poisonous dose, a dose that will ultimately kill it, without its coming to?—That question I think had better be asked of some physiologist.

7332. Is it not rather material in answer to what Sir William Church asked you? Supposing that a dog lived for half an hour under a dose that was really poisonous—supposing it had resisted that poisonous dose, could it not be operated upon during that half hour?—It is very difficult for me to answer. Witnesses often answer questions in a few words which give quite a wrong impression because they are not

allowed to state their whole point of view, and I do not wish to give an erroneous impression.

7333. (*Sir Mackenzie Chalmers.*) May I take it that your point is that if a large dose of morphia is given the animal may die, but that up to the point of death it may feel pain?—That is my point; and that is brought out by the evidence of Claude Bernard and many others.

7334. That is your point?—Yes.

7335. (*Sir John MacFadyean.*) Is the contrary impossible?—May I also state that large doses of morphia have been known to act as a violent stimulant?

7336. (*Sir William Church.*) I beg your pardon, but the question I asked you was in the case of a dose which is perfectly fatal, when the animal is not excited, but when it has become perfectly unconscious. Do you think that animal feels pain?—Then my answer is that we do not know, and that the evidence is overwhelming on the side that that animal may be feeling pain although it may be lying perfectly still.

7337. Do we or do we not know whether a man in that condition feels pain?—I think we know that a man fatally poisoned with morphia does not feel pain.

7338. Then on what grounds do you infer that an animal in a similar condition feels pain?—Because morphia, as Professor Hobday points out, acts differently on dogs and men. He says that dogs are extraordinarily insusceptible to morphia.

7339. Then your answer to me is that Professor Hobday says so?—Yes.

7340. (*Sir John MacFadyean.*) Do you know whether Professor Hobday has ever administered a poisonous dose of morphia to a dog? Are the experiments that he has carried out not cases in which he has employed non-poisonous doses? He dare not employ a poisonous dose on his patient?—That I do not know.

7341. But that is very material if you quote his evidence as being conclusive?—May I also say that such terribly poisonous doses of morphia would interfere entirely with physiological experiments? There again I quote Claude Bernard and various other authorities. For instance, experiments on the secretion of the salivary glands are frustrated by too much morphia or opium; and I think if a dog were poisoned to such an extent with morphia the object of the experiment would be defeated.

7342. (*Sir William Collins.*) Do you quote Professor Cushny to show that if it be true that a dog under morphia betrays an exaggerated sensibility, at any rate in that stage, it is not in an anæsthetised condition?—Yes, that is why I quote Professor Cushny; and I have one more sentence from Professor Cushny's book relating to morphia upon cats. May I also say that the opinions of Professors Charles Richet and Dastre in France, and Professor Sollmann in America, are that morphia is not an effective anæsthetic? I quote Professor Charles Richet especially on the point of anæsthetising animals in laboratories.

7343. (*Sir William Church.*) Do you mean by these gentlemen saying that it is not an anæsthetic that if it is used in large quantities it does not prevent the animal feeling pain?—I mean to say that if large quantities would induce anæsthesia, I am sure that these gentlemen would not say so definitely that it is not an anæsthetic. Professor Cushny gives his experience of the effect of morphia on cats and other animals and we learn that "In the cat and in all the other *felidæ*, and in the horse and ass morphin seems rather to increase than to diminish movement. The animal runs about the room, or in a circle, and seems unable to remain at rest for a moment. At the same time a depression of the intelligence and of the power of perception makes itself manifest, for no definite attempts at escape are made, and obstacles are not avoided so carefully as by the unpoisoned animal. Eventually, convulsions similar to those seen after strychnin are developed" (p. 207). In connection with that, but I think the Commission will not care to hear it, I have brought considerable evidence to show that a great many experiments are performed on cats in this country under morphia; but I will leave that as there is no doubt thrown upon it, I should think.

7344. (*Colonel Lockwood.*) Under licence, I suppose?—Yes, under licence.

7345. (*Chairman.*) At any rate, if they are we should have the witnesses who were present at them to tell us what took place?—But it is not illegal in England, of course, to use morphia as an anæsthetic, and my point of view rather is that it should be illegal.

7346. (*Sir Mackenzie Chalmers.*) It is not a prohibited anæsthetic?—No. My point of view is that under the present Act of 1876 it should not be counted as an efficient anæsthetic. That is why I have brought all this evidence forward.

7347. We have been told that morphia is very often given as aiding other anæsthetics which are always given. You do not object to that?—I think one can have no objection to it when merely preparatory to anæsthesia, but I object to experiments which are done only under morphia or under morphia and curare, and especially on cats. Professor Hobday I know said to me that morphia is not an anæsthetic for dogs, and still less so for cats.

7348. (*Sir John MacFadyean.*) In non-poisonous doses?—Professor Cushny says that the larger the dose the more exaggerated the sensibility.

7349. But Professor Hobday did not say that?—But Professor Cushny does. I did not discuss that particular point with Professor Hobday, but I have no doubt that he would say the same. If it acts on cats in that way, so that they are unable to remain at rest for a few moments, it cannot surely be an anæsthetic. I should now like to be allowed to draw the attention of the Commission to the difference between vivisectional operations and surgical and veterinary operations under anæsthesia, as attempts are often made to identify the two.

7350. Have you yourself attended at some veterinary operations?—I have attended at some veterinary operations, and I have also attended some vivisectional operations, and surgical operations too, and therefore I am anxious to draw a distinction. Veterinary operations are not disturbed, but aided, by deep surgical anæsthesia. Vivisectional operations, dealing as they do with the delicate measuring of functional activities, are often disturbed by deep anæsthesia. Suffering after veterinary operations can be mitigated in every way. Suffering after vivisectional operations often forms part of the experiments, its causes and development being carefully recorded. Through the courtesy of Professor Hobday I was some time ago allowed to be present at an abdominal operation on a dog which was in a state of perfect surgical anæsthesia, in which every sign of consciousness or pain was entirely absent, and the dog lay in an absolutely limp and motionless condition through the action of chloroform administered by a special anæsthetist who devoted his whole time and attention to this, and who kept the anæsthesia uniform by constant and careful doses of the anæsthetic. The difference between this anæsthesia and conditions which I have seen in the physiological laboratories is very great. The whining and struggling dog which I saw on February 26th, 1903, at the Physiological Laboratory University of London, in which the abdomen had been opened, the intestines pulled over to the right side, and the kidney placed in an oncometer, the neck opened, and which was subjected to the usual stimulation of nerves, compression of veins, and injection of foreign substances, is an instance of a victim of the light anæsthesia which the vivisector prefers.

7351. (*Colonel Lockwood.*) That you saw yourself?—Yes. It is described in the "Shambles of Science" under the title "A Troublesome Dog"; it was troublesome because it whined.

7352. (*Sir John MacFadyean.*) When you say it was a victim, you intend to suggest that it was conscious of pain?—I intend to suggest that so far there were signs of consciousness.

7353. What do you wish us to believe, because there is no point in it if the animal was quite unconscious?—The difficulty of proving this is that nobody, neither the Commission nor I, nor any vivisector, can say whether that particular dog felt pain. I simply say that the dog whined and cried and seemed to be conscious, and we never can go by any other signs. How can we know whether an animal feels pain; we can only go by signs?

7354. I merely asked you whether you wished us to believe that the animal was conscious?—I wish to point this out as a typical instance of the kind of anæsthesia that is used in vivisectional experiments, and the great difference between that anæsthesia and the anæsthesia that I saw in Professor Hobday's surgical room. The object of the veterinary surgeon is generally the alleviation of pain and suffering; the object of the experi-

Miss L. Lind-af-Hageby.

1 May 1907.

mental physiologist and pathologist is sometimes the production of pain and suffering. And this brings me to my next point—namely, that books intended for students do not even avoid referring to the production of pain in animals as part of the ordinary routine of experimental experience. In his book "The Elements of Human Physiology" Professor Starling speaks of the stimulation of the (sensory) afferent nerves of the heart (page 249) in these words: "We may investigate their functions by stimulation of the central ends of the divided nerves. They may produce one or more of four effects: (i.) Pain as evinced by the movements of an animal not fully under the influence of an anæsthetic (we should be more correct if we said that stimulation of these nerves produced reflex movement)." Professor Starling no doubt speaks from personal experience here, and yet he has told the Commission, in answer to Question 3451, that though he has been engaged in the experimental pursuit of physiology for the last 17 years, he has never seen pain inflicted in any experiment on a dog, cat, or rabbit. On page 373 Professor Starling enlarges upon his knowledge of the effect of painful stimulation, and tells us that "any painful stimulation of a sensory nerve, especially in the abdomen, excites a reflex inhibition."

7355. (*Chairman.*) I do not know enough of these terms, but when he uses the word "reflex," does that imply that they do not feel pain?—That has really very little to do with it. A reflex movement may be painful or it may not.

7356. It may be painful?—Yes, but he speaks of the production of pain specially.

7357. (*Dr. Gaskell.*) On what page?—On page 373, "painful stimulation of a sensory nerve"; and on page 249. Another book which refers to the production of pain in a similar way is Mr. Hodgkinson Lack's "An Introduction to Physiology" (published 1905), and written for the student and future medical practitioner. This book is certainly not a very important one, but it is written in a way which is characteristic of the spirit with which even the younger generation of vivisectors treat experiments upon live animals. Anæsthetics are not mentioned, and animals are written of in this style (page 68): "Take a healthy frog and dissect out the steadily beating heart." On page 73, on afferent nerve fibres (vaso constrictor): "Dissect out the cervical sympathetic in a rabbit. Section it, and the arterioles in the rabbit's ear relax, and the ear becomes flushed with blood." Or (vaso dilators): "Dissect out the chorda tympani in a dog, and section it, no marked changes will be noticed in the submaxillary gland" (page 74). Or page 124 (the function of the renal tubules): "An animal is taken, and the medulla is sectioned below the level of the vaso-motor centre, and therefore there is a fall in general blood pressure. . . . The animal is kept alive by means of artificial respiration." On pages 52-53-54 stimulation of a spinal nerve and its roots is dealt with, and the author gives a diagram with indicatory letters, and points out in a table the various effects of stimulation, pain being several times included among the results. I wish specially to emphasise that the indifference or the callousness which generally characterises these books must tend to lessen the humane feelings of, and to demoralise, all those who take up the study of physiology, and also that the conspicuous absence of special warnings against cruelty in a field of research, manifestly open to abuse, even in the eyes of those who do not consider it inseparable from cruelty, brings proof that the boasted humaneness of the modern vivisector is an attempt to quiet the public, and to allay the steadily-growing opposition to vivisection.

7358. (*Chairman.*) Do you read that last passage as an instance of callousness?—I read the last passage and refer to the last book as an instance of callousness.

7359. Why? It is written, I suppose, for medical purposes?—It is written for the student and future medical practitioner, and is meant to serve as an incentive to further study.

7360. But what is there that is callous about it if he is actually describing the facts? He is not, as I understand, using any brutal expressions about it; he is describing it in the ordinary way?—The callousness would come in in the fact that this is a book which is supposed to be an educational work, and that, whilst he has time to write of all the details of the experiment, the curare and artificial respiration, he does not even mention anæsthetics throughout the book.

7361. He does not need to mention them at that time?—Also the style in which the animals are spoken of: "Take an animal." "Take a healthy frog, and dissect out the steadily-beating heart."

7362. Supposing you were describing the action of a cook, or of somebody who is recommended to kill a fowl in a particular way, you would not expect the cookery book to give directions to the cook to be particularly careful over it. I cannot see where the callousness comes in?—It is all, of course, a matter of opinion. What seems callous to some people does not seem callous to others. I can say confidently that to the humane section of the community this book would seem callous because of the omission of any reference to anæsthetics.

7363. It does not seem callous to me; and everyone who does not agree with your view of that passage is inhuman, I suppose?—No.

7364. (*Sir John MacFadyean.*) Might I ask the name of the author of that book?—I have said that this book is not among the most important ones. It is Mr. Hodgkinson Lack. His name appears in the Medical Directory for 1905, but I cannot find it in the Directory for 1907. However, he was a licensed vivisector in 1905. I believe he lives in Edinburgh, but I do not know much about him. I only know that the "British Medical Journal" in a review some time ago did not seem to admire the book, but said that it was written for cramming.

7365. I was just going to ask you, was it not a cram book when students are expected merely to get up facts with regard to results?—Even if it is ——

7366. Do you suggest that it is an invitation or incitement to students to go and do the things which are described in it?—I suggest that, because the author himself says that the book is meant to serve as an incentive to further study, and as an incentive to further study I maintain that it could have been accompanied by a little humane counsel or a few words at least about anæsthetics.

7367. (*Sir Mackenzie Chalmers.*) Is there not a distinction between study and research?—Yes, there is, but thoughts generally lead to action, and therefore I would say that humane thoughts ought to prevail in these books, as actions are the fruits of thoughts.

7368. (*Sir John MacFadyean.*) Do not you think that the author was much less ambitious, that he merely expected his book to serve as a cram?—His ambition did not prevent him speaking of curare and artificial respiration. I wish his ambition had led him to talk of anæsthetics, too, which it might easily have done

7369. (*Chairman.*) However, you quote that as a strong instance of the callousness of the medical profession?—No, not of the medical profession. I was speaking of vivisectors.

7370. (*Sir Mackenzie Chalmers.*) Physiologists?—Yes, licensed vivisectors.

7371. (*Chairman.*) Who are supported by a large majority of the medical profession?—It remains to be seen, of course, how many they are supported by.

7372. I did not know that it was disputed that they were supported by a large majority?—No, perhaps not.

7373. (*Sir William Church.*) All these text books and various other books that you have quoted you quote to show that they do not suggest humanity to students, but if anything you say that they would rather lead to callousness on the part of students, because, in your opinion, they are calculated to incite students to do these operations for themselves, and also to cause them to be callous as to the pain that they may inflict?—I have not quoted them for the purpose of showing that they may incite students to take up illegal vivisection; that has not been my point of view; but I have quoted them to show that the general tendency in them is one of disregarding altogether all moral or humane considerations, and that the study of physiology at the present moment cannot but be entirely indifferent to the humane and moral claims.

7374. But then I want to ask you further whether it is not the fact that anybody who wishes to experiment or to witness these experiments has to either perform them or see them done in a licensed laboratory?—Yes.

7375. And do you mean us to infer that the tone of the directors of these laboratories is one tending towards cruelty?—In quoting these text books I have criticised the tone of them, but I am quite prepared, if I am asked the question, to say also that in my personal experience I have found nothing in the teaching of physiologists which justifies the claim that is made that vivisectors nowadays do everything to further humaneness. I have seen nothing which justifies the claim of vivisectors that the modern vivisectors are endeavouring to inculcate humaneness. That is the red thread in that part of my evidence.

7376. The object of your having quoted all these textbooks to us this morning is to show that the directors of the physiological laboratories in general are regardless of the sufferings of animals, and do not impress upon their students the necessity for humanity at all?—That cannot have been my object, because the authors of these textbooks are not all directors of laboratories—at least, I have not put that forward; but I have put forward these books, and have quoted from them to show the lack of any signs of a wish to inculcate humaneness in the theory and practice of experimental physiology.

7377. Why should they, because all this vivisection to which you allude goes on in laboratories where, of course, the experimenters come into communication with the directors of those laboratories, and generally—at least, I believe so—they receive advice as to their action with regard to animals?—That claim might have been put forward if vivisectors had not put forward this other claim on which I base my statement, that everything is done to inculcate humaneness. And then, further, everything is also done to make young students interested in experimental physiology, to take it up. Professor Starling has advocated his views before the Commission that students should first attend vivisectional demonstrations, and further take up vivisection themselves for the purpose of acquiring manipulative skill, and under those circumstances, as vivisectors are so anxious to spread their teachings and to reach the younger generation, I maintain that their indifference from the point of view of humaneness and mercy and kindness and all such things shows that they are indifferent on that point, an indifference which sometimes amounts to callousness.

7378. You would not go so far as to say that the directors of physiological laboratories generally teach their students that they should study by means of scientific experiments, perfectly irrespective and regardless of pain, that they need not consider that at all. That is rather the effect of your remarks this morning on my mind?—I do not think I have suggested that. In fact, my suggestion is not that there is any deliberate encouragement of cruelty, but that there is an entire indifference to the humane side of the question.

7379. (*Chairman.*) Will you proceed?—I wish specially to emphasise that the indifference and callousness which generally characterise these books must tend to lessen the humane feelings of and to demoralise all those who take up the study of physiology, and also that the conspicuous absence of special warnings against cruelty in a field of research, manifestly open to abuse, even in the eyes of those who do not consider it inseparable from cruelty, brings proof that the boasted humaneness of the modern vivisector is an attempt to quiet the public and to allay the steadily growing opposition to vivisection. Among such demoralising literature, a book just published by Messrs. Macmillan and Company, in London, is conspicuous. It is "Collected Papers on Circulation and Respiration," by Sir Lauder Brunton. In 1907 Sir Lauder Brunton calmly publishes a paper (included in this volume) on "Experiments on the Influence of Digitalis on the Pressure of Blood in the Arteries" (page 103). (I have that book here, too) which, it is true, records experiments performed before the present Act, but which, nevertheless, are of a peculiarly brutal nature, and couched in words which cannot but give the direct lie to the assertions of vivisectors, that the old-fashioned experiments would be met with disgust to-day. These experiments, which involved opening the neck of dogs and sheep, exposing the carotid arteries, and inserting the nozzle of a hæmadynamometer, and injecting the digitalis through the open jugular vein, have, I believe been referred to before this Commission by Professor Cushny as having been done under anæsthetics (Q. 4655). Professor Cushny also asserted that had no anæsthetics been used the experiments could not have been performed owing to the movements of the animals. That is at numbers 4660A and 4663, and also that the animals were not allowed to recover. The following extracts from Sir Lauder Brunton's own paper show the inaccuracy of Professor Cushny's statements: Experiment I., November 25th, 1865——

7380. (*Chairman.*) But really it is extremely immaterial whether an operation before 1876 was or was not performed under anæsthesia; it was not illegal at the time, and it is taking up time unnecessarily. You said something about Sir Lauder Brunton alluding in brutal terms to some operations before 1876. Will you read what those brutal terms were?—I say my point of view is not that these experiments were performed in 1865. My point of view is that the republication in 1907 proves that vivisectors are not ashamed.

7381. I quite understand that, but you said that it proved that he was callous and brutalised on the subject of operations, because he spoke of these operations which were before 1876 in brutal terms?—Yes.

7382. What are the brutal terms?—I am coming to them.

7383. Would you come to that—because that is the only material thing?—I said that these experiments were nevertheless of a peculiarly brutal nature, couched in words which cannot but give the direct lie to the assertions of vivisectors that the old-fashioned experiments would be met with disgust to-day.

7384. Will you refer to the terms in which he speaks of them?—May I refer to their peculiarly brutal nature? The experiment was performed on a pointer. "It was tied down to a table and chloroform administered while the carotid was being exposed." This animal is described as struggling (p. 105). The same animal was used for Experiment II. on November 29th. The experiment began at 1.58, and among the author's remarks I note the following: "Time, 2.53.—Dog appears to be sick, but does not vomit, the muzzle preventing him from opening his mouth at all. Dog moans. Time, 2.55.—Groaning much increased and louder. 2.56.—Appears to be endeavouring to vomit. 2.59.—Convulsions. Stoppage of heart's action. Dog dead." The post-mortem revealed that "The veins and right side of the heart were engorged and swollen, stuffed like sausages, as Caspar describes it." On the same day, Experiment III. was performed on a full-grown sheep. The experiment began at 8.35 p.m., the sheep being tied down on the table. No chloroform was given. Extract from remarks: "9.22——

7385. (*Sir William Collins.*) Does Sir Lauder Brunton say that no chloroform was given?—No chloroform. I have the book here.

7386. (*Sir Mackenzie Chalmers.*) What is the date of it?—1865.

7387. Were they in England?—Yes.

7387A. (*Sir William Church.*) Was it not in Scotland, to be quite correct?—They were in Britain; they may have been in Scotland. "9.22" (this is a sheep).—"Animal excited by examining the wound. 9.45.—Sheep struggling. 9.47.—Sheep struggles." The next morning, on November 30th, the sheep "seemed still much depressed," and between 1 and 2 p.m. it was again tied on the operating table. This time chloroform was administered, and the other carotid opened. Extract from remarks on this experiment: "2.11 p.m.—Sheep appears completely free from the effects of the chloroform. 2.14.10.—Violent struggles take place. 2.16.15.—An apparently convulsive movement of the head. 2.17.10.—Violent struggles. Another struggle. 2.22.10. — Animal violently struggling. 2.33.—The sheep was allowed by all to be dead." On December 20th the fifth experiment was made on a large dog.

7388. (*Chairman.*) Is this the same sort of thing that follows?—Yes. I will not read it all; I will just give an extract. On December 20th the fifth experiment was made on a large dog, a kind of bloodhound. Chloroform was given, but Sir Lauder Brunton explains that after he had exposed the carotid, which lay very deep, the dog was seized with convulsive tremors. Then he describes the course of the experiment in these words: "Howling loudly, as if suffering much" (p. 111). Then he speaks of the eye, and says: "Pupil less contracted, seems normal, sensitive." Another experiment—Experiment VII.——

Miss L. Lind-af-Hageby.

1 May 1907.

7389. I do not think that multiplying instances is any good. Surely three are enough?—It is characteristic that in describing another experiment he states that "the dog appears to be free from chloroform, and seems to feel pain, as he groans" (p. 121).

7390. That is exactly the same thing; but those are operations that cannot be performed now; the Legislature thought they were improper and cruel, and put a stop to them; therefore it does not help us much now to describe those experiments. But, supposing they had to be described, how would you describe them in different language? Do you say that it is inaccurate language?—I would never publish them now. I should have been thoroughly ashamed of them.

7391. Do you mean to say that in an article to be read by scientific men, you think that a scientific man is doing something brutal in publishing it?—I think so, if his book is likely to be read by a very large number of students. And, further, the Commission has heard these same experiments described from the scientific point of view. That scientific view has been put before the Commission by Dr. Cushny, and therefore I beg leave to put our view before the Commission. I put them before the Commission from the moral point of view; they are the same experiments, and from the moral point of view I say that they are repellent, and I care not whether they are useful or not; from the humane point of view they are utterly worthy of—I will not use a term.

7392. They are illegal now. The law has said that they are illegal on the ground that they are cruel, and there is an end of it. I do not see the object of reading out an account of them. I thought you read it for the purpose of showing that Sir Lauder Brunton, as a leading physiologist, rather gloated over things of this kind when he described them. I can see nothing except an ordinary description. If these things are to be described at all, they seem to me to be described in the ordinary language that you would expect from an educated man?—I read them simply as being material to my point of view, to show that the modern literature of vivisectors and physiologists tends to demoralise those who read it, and I brought, as the very strongest instance I could bring, the republication in 1907 of such terrible experiments in a book which can be bought for 7s. 6d. by any medical student.

7393. (*Colonel Lockwood.*) And to destroy the opinion that vivisectors wish to get abroad that they are humane in their ideas?—Yes. It has often been said that the old-fashioned experiments would never be allowed; that they would be met with disgust and hatred to-day.

7394. (*Sir William Collins.*) Are these the same series of experiments in regard to which Professor Cushny answered the noble Chairman, at question No. 4660a, by saying, "I am quite sure Brunton would use anæsthetics"?—Yes.

7395. (*Sir John MacFadyean.*) Is your train of argument this: that, assuming that in the past painful experiments, which would not now be allowed, had really contributed useful knowledge with regard to the cure and prevention of disease, all reference to those experiments and to the facts they disclosed should be blotted out of published books?—My point of view is that the vivisector who is responsible for them would certainly not republish them in 1907 if he really had any feelings with regard to humaneness, or want of humaneness, in carrying them out.

7396. So that you would really establish a sort of Press censorship to obliterate all record of any past painful experiments, although they had contributed very useful knowledge?—I think that certainly from an educational point of view it would be much better and more in accordance with the claims made by vivisectors.

7397. (*Chairman.*) That, I understand, ends that part of your evidence?—That ends that part.

7398. And we come next to your own experience of experiments?—Yes.

7399. (*Chairman.*) Coming to these experiments described in the "Shambles of Science," it struck me that it would be a convenient course (but if it is not you will tell me so) if I asked you—to take as an instance the "Painless Experiments" whether as regards the facts stated in your book you adhere to the statements you made there, or whether you wish to alter anything?—No, I adhere to everything.

7400. Then I will take it in that way, and any questions can be asked you upon it with a view to making you modify or explain anything?—If you please.

7401. I will take it very shortly then. You have already told us that you proceeded to attend a series of lectures in 1902, which you afterwards described in the book called the "Shambles of Science"?—Yes.

7402. The first of them, I see, is called "Painless Experiments," at page 12; I have got the older copy?—Yes; page 11, I think.

7403. That was an experiment on a frog, and I think what you say there is that the frog was not properly pithed, or, at any rate, that sufficient was not done to destroy its nervous sensation—its feeling?—It was one of the ordinary experiments on frogs which are not properly pithed; and I have some evidence that I am very anxious to bring out in connection with that very subject, if I am allowed to do so.

7404. If it is what somebody else says about it on that particular case, I am afraid we must have the witness before us. We cannot have your account of what another witness may say about it?—It is a theory that I wish to bring forward in support of what has been said in this chapter on "Painless Experiments." It is a theory of my own, but it is one which is supported by other people.

7405. As to what happened to the frog?—No, not as to what happened to this particular frog, but as to frogs generally in physiological laboratories.

7406. We shall get into some very wide questions if we go into that. We had better treat it simply. You can hardly call that in support of your own account of what took place?—It is in support of what took place, and it is solely in support. It is in support of my account of what took place; but I can very well, if it is the wish of the Commission, wait and answer all questions first.

7407. You say that it applies to this particular case?—It does.

7408. Then we will take it now?—This experiment describes certain very ordinary experiments upon frogs which are often performed in physiological laboratories, and which form the very ABC, if I may use that expression, of experimental physiology. These frogs were, in the opinion of orthodox physiologists, incapable of feeling pain because the brain had been destroyed. The theory I wish to bring forward is my own firm belief that it has not been proved that a frog is incapable of feeling pain so long as it is capable of these complicated purposive movements which show sensation and volition, and several other qualities, which, at any rate, cannot be associated with any animal that is said to be dead—because very often these frogs are talked of as being "dead"; and my contention is that these frogs are not dead. That is my first point. And the second is that it is not proved that they are incapable of feeling pain.

7409. You have not, I presume, tested your theory by any experiments on frogs?—No, I have not. Then, in connection with that, I think that Professor Starling's evidence before the Commission brings out very clearly that students are at the present moment allowed to experiment upon frogs. I have the exact reference here.

7410. (*Colonel Lockwood.*) Without licence?—Without licence—because students do not generally hold a licence. It was in answer to Question No. 3747 that Professor Starling said of students: "At present they have to get a large extent of their practical experimental knowledge from a frog; a frog is a long way from man." And then he goes on to advocate that students should be allowed to experiment on a rabbit. This statement seems to show clearly that Professor Starling does not consider it a contravention of the Act that students should at present be allowed to perform experiments themselves on frogs. I find similar statements in other books, especially in a book called the "Physiological Action of Drugs," by M. S. Pembrey and C. D. F. Phillips, in which there are statements in the preface which show that physiologists at the present moment look upon experiments on frogs as legitimate for students to perform. Now, the Act applies, so far as I understand, to all vertebrate animals, and I am

Miss L. Lind-af-Hageby.

1 May 1907.

not going to repeat the mistake which I believe the Editor of the "British Medical Journal" made in 1897—I suppose it was a slip *—of saying that the frog is not a vertebrate animal. The frog is supposed to be a vertebrate animal, and as such I maintain that the frog should come within the influence of the Act of 1876.

7411. I daresay you will be asked some questions about your account of what you saw by various Commissioners; I do not propose to ask you any other question myself?—May I say further in connection with this that the phenomena that we describe in this chapter are quite ordinary phenomena? There is nothing extraordinary in them. Brainless frogs are capable of jumping and croaking; they can feed by catching passing insects, and the longer they live the more do they resemble intact animals. The whole question whether brainless animals are capable of feeling pain is an exceedingly important one in connection with antivivisection and the whole vivisection question. The frog is so low down in the zoological scale that the spinal cord is capable of taking up the functions of the brain when the brain has been taken away; and we find this in a lesser degree the higher up we go in the zoological scale; but even dogs can live without their brains. Goltz had a dog which lived more than a year and a half without its cerebral hemispheres. He believed that this dog had lost understanding, reflection, and memory, but not sensation—that it was capable of emotions and voluntary power, that hunger and thirst were present. These dogs of Goltz experienced satisfaction when fed, became angry when attacked, saw a very bright light, avoided obstacles, heard loud sounds, and could be awakened by them. Professor Sherrington, in a well-known book, called "Schäfer's Text Book of Physiology," on the subject of cutaneous sensation, refers to the dogs that were experimented upon by Goltz in these terms: "The dogs from which Goltz has removed the cerebral hemispheres reacted to 'painful' stimuli in a way which was interpreted as evidence of physical pain." I have some further extracts from books by Dr. Ferrier and Professor Starling to show that rabbits deprived of their brains are capable of feeling pain.

7412. (*Sir Mackenzie Chalmers.*) When deprived of the brain, or a portion of the brain?—The whole brain. Dr. Ferrier says, on page 146 of his book, "The Functions of the Brain," a very well-known book: "Animals deprived of their cerebral hemispheres are still capable of exhibiting, in response to various forms of sensory stimulation, special and general, reactions, more or less complex, which do not at all differ in character from those which we associate with feeling or emotion." . . . Rabbits scream piteously, and exhibit the various signs of agitation characteristic of intense pain if their toes are pinched, or any sensory nerve severely stimulated." And Professor Starling, in his "Elements of Human Physiology," though not dealing with it from the psychological point ——

7413. (*Chairman.*) We are getting rather a long way from the frog in the second experiment?—It all bears upon the question.

7414. I think it is getting rather far from that question, because I presume there is no doubt that physiologists would agree that dogs and rabbits come under the Act?—Yes.

7415. And any operation of taking out their brains would be something done under the Act?—May I just bring one instance? There is a tendency at present, just because anæsthetics are so distasteful to vivisectors, which I have already referred to, to perform experiments on animals that have been deprived of their brains; and the vivisectors would then consider that those experiments are absolutely painless, and they would no doubt be performed under licence alone—in other words, counted as equal to employing an anæsthetic. Thus Dr. T. G. Brodie and Miss Winifred C. Cullis performed some experiments on the secretion of urine (they are described in the "Journal of Physiology" of May, 1906), and they say: "We therefore" (that is because anæsthetics were for some reason not suitable) "worked upon animals (dogs) which have been killed by pithing." Pithing there does not include, evidently, the destruction of the spinal cord; because I admit that an animal that has had its brain and spinal cord destroyed is incapable of feeling pain; but my point is that it is not proved that animals which only have had the cerebral hemispheres removed are incapable of feeling pain. Dr. Brodie, after saying first, "We therefore worked on animals which have been killed by pithing," continues: "Such animals recommence to breathe within a few minutes. . . . Such animals survive in this condition for some four to eight hours." As they had been "killed" in this case, that expression at least seems somewhat incongruous.

7416. (*Colonel Lockwood.*) What page is this?—"Journal of Physiology," Volume XXXIV., number 3, 1906, page 234.

7417. Have you got it here?—Unfortunately I have not brought it, but I can send it to the Commission. I believe that Miss Winifred C. Cullis, who was demonstrator of physiology at the London School of Medicine when I attended lectures there, held no licence; and I should think that if she holds no licence this experiment would simply be counted at present as an experiment not within the Act, because the dogs are supposed to have been killed. Yet they survived for from four to eight hours.

7418. (*Chairman.*) Were experiments tried upon the dogs during those four or five hours?—Yes.

7419. (*Sir William Church.*) Would you tell the Commission how they were enabled to carry on a certain amount of vital action?—They were enabled because according to Goltz and other observers a dog can be kept alive for 18 months without its brain.

7420. But how were these particular dogs that were experimented upon kept so that the vital action could go on during the four to six hours during which the experiments were done?—I think that vital action goes on perfectly if the cerebral hemispheres have been removed.

7421. This has nothing to do with the cerebral hemispheres. You tell us that these dogs were pithed, and then Professor Brodie and Miss Cullis carried out some experiments during four or six hours, I think you said, on the urine?—Yes.

7422. Would you tell the Commission how these dogs were enabled to go on performing certain vital functions?—I do not think anything is said in that chapter as to how they were enabled to do so.

7423. You have not tried to inform yourself of the reason why these dogs differed from any other dog that is pithed and then kept alive. Are you not aware that pithing is an immediately fatal operation in an animal if you leave it alone. You understand what pithing is?—Yes, of course.

7424. Cutting across the spinal cord?—No, the cutting may not be across the spinal cord. That is just another point that I wish to bring out before the Commission; that pithing is a word which covers so very many things. Real pithing, I maintain, means destruction of the cerebral hemispheres and the spinal cord.

7425. Will you tell us what it meant here in this particular case; that is what we want to know?

7426. (*Sir Mackenzie Chalmers.*) Do you know how this dog was pithed?—No information is given as to how it was pithed, and I cannot tell the Commission. I used the words which were used by Dr. Brodie and Miss Cullis.

7427. (*Chairman.*) Does Dr. Brodie say the dog was pithed?—He uses the word "pithed" exactly as I read it. What I wanted especially to bring out was that pithing is used for a great many different things. It is used by some vivisectors and physiologists in the sense, which I believe is the accurate and proper sense, of the total destruction of the brain and spinal cord. It is used by others merely to convey destruction of the cerebral hemispheres.

7428. (*Sir William Church.*) Would you kindly tell us the different physiologists who use the term in those different senses?—I can if you will allow me time to look it up in the books which I have brought.

7429. I do not mean now, but will you send it to us afterwards?—Yes; I thought of preparing a list of them, and then I thought it would not be required.

7430. (*Chairman.*) Perhaps you will give us a note of it later on?—Yes; and I will also look up that par-

* *See "Zoophilist" of July, 1897, and June, 1902.—L. L.-af-H.*

Miss L. Lind-af-Hageby.

1 May 1907.

ticular point as to Dr. Brodie and Miss Cullis's special form of pithing here. I will endeavour to get it for the Commission.

7431. You mean what is referred to in the chapter on painless experiments?—Yes.

7432. Then the next chapter is: "An Experimental Production of Blood Clotting by Injection of a Nucleoproteid." The suggestion there, I think is that the rabbit which was being operated upon gave signs which satisfied you that it was not being adequately anæsthetised?—Yes, Mr. Thane, the Inspector under the Act of 1876, has referred to this chapter before the Commission, and he has characterised our suggestion contained in this sentence: "And would not the tetanic spasms that followed counteract the effect of a possible anæsthesia?" as ridiculous; and he then goes on to quote from a paper by Professor Halliburton, published in the "Journal of Physiology," Volume XVIII., page 138, an account of the very same processes, though couched in more scientific, and, of course, non-sympathetic language. What we call struggles is there interpreted as "slight stretching movements." We say "The eyes become bloodshot and start from their sockets"; whilst the scientific terms are: "Extreme exophthalmos and dilation of the pupils." We describe that the animal fell back dead, as it was supposed, and that it resumed its struggles after having received a stimulus; whilst the scientific paper admits the very same thing by saying that "sometimes after ceasing to breathe for a minute, the animal gives a few breaths more, and sometimes it resumes breathing normally." If Mr. Thane had taken the trouble to quote other paragraphs from the "Journal of Physiology," describing similar experiments with blood-clotting by Professor Halliburton,* he would have found the phenomena which we describe and insist on describing as struggles, referred to as "pronounced stretching movements of the fore and hind limbs which occur immediately before the death of the animal"; and in the case of a large black dog, weighing 30 lbs., experimented upon at 4.44, the result was stretching movements and spasms. The struggling movements are referred to as becoming more pronounced at 4.57, whilst at 5 o'clock an additional injection resulted in extreme stretching movements. An absolute line of divergence between extreme stretching movements and struggles might be difficult to find. The spasms described by Professor Halliburton in his paper tally with the spasms described by us. Mr. Thane considers the suggestion that tetanic spasms might counteract the effect of a possible anæsthesia ridiculous. I maintain that it is not impossible. Our suggestion is intended to convey that the presence of convulsions indicated that the animal was not under the influence of an anæsthetic. The fact that anæsthetics are constantly used as anti-spasmodics and known to allay convulsions generally, indicates that deep anæsthesia and convulsions are two incompatible conditions. In the "British Medical Journal" for June 29th, 1901, there is a description of an experimental inquiry into the pathology of gastric tetany by Professor Halliburton and Dr. McKendrick. Tetany fluid, prepared from the vomit of a patient suffering from gastric tetany, was injected into a cat under anæsthesia, and the writers remark that "no spasms or convulsions were produced, whether these would have occurred had not the animal been anæsthetised it is impossible to say." These words show that Professor Halliburton does not consider it impossible that the anæsthesia was responsible for a suppression of spasms, which leaves room for the counter suggestion.

7433. No doubt questions giving an opportunity of making that statement would have been asked you by other members of the Commission. I think perhaps as you have told us that you adhere to your acounts of these experiments, that will be the shortest way of dealing with them. I put the question to you in that way so that there should be no mistake as to what is meant by them. That deals with the experiments in the chapters beginning with "painless experiments," and ending with "a grand demonstration"—that is the last of the pure descriptions of experiments. You say that those accounts are correct?—Yes.

7434. Then I think I will not ask you any further questions, but other members of the Commission may desire to do so, and if, when they have asked them, there is something that you wish to add in explanation you will have an opportunity of doing so?—If you please.

7435. (*Colonel Lockwood.*) You maintain that the quotations given in the books you read tend to show that science, and not humanity, are inculcated in the physiological books of which you have given us extracts?—Yes, that is what I intend to convey.

7436. That is what you gave us those extracts for?—Yes.

7437. Have you any reason to believe, from personal knowledge, that the law as it at present exists is evaded in the laboratories?—Of course, several of the accounts in the "Shambles of Science" would tend to show that the law, if not evaded, as it stands admits of cruelty.

7438. We have had some conversation about light anæsthesia, and you read from some books on the subject of light anæsthesia as, I suppose, opposed to complete anæsthesia. But would you acknowledge that light anæsthesia may produce complete insensibility as well as deep anæsthesia?—I would not acknowledge it, and I do not believe that surgeons as a rule operate under light anæsthesia. There were some very interesting letters on that subject, published some time ago (I have the references if they should be required) to the effect that surgeons as a rule in our great hospitals do not operate under light anæsthesia; and one surgeon in particular, Mr. Edmund Owen, in referring to a certain number of operations which, from their nature, cannot be performed under deep surgical anæsthesia—that is operations on the throat, on the palate, and certain other operations—ends his letter to the "Times" by saying: "Why should it be necessary to spread out these hideous things before the public gaze?" (March 15th, 1902). And another of these surgeons said that operations under incomplete anæsthesia would be "as embarassing to the operator as painful to the patient."

7439. If done without anæsthetics?—If done under light, incomplete anæsthesia.

7440. Therefore, what you maintain is that operators on mankind would never use light anæsthesia; they would always work under complete anæsthesia?—They would always endeavour to get complete anæsthesia except for certain operations where such anæsthesia would be dangerous.

7441. But they are not averse to using light anæsthesia on animals from the fear that their experiment might be spoiled if they used complete anæsthesia? That was your point, was it not?—Yes, that is my point.

7442. You have seen some operations on animals?—Yes.

7443. Have you ever seen a distinct breach of the law that you could point out to us?—Of course, I do not know if you can go over the whole trial again, but there was, in my opinion, a distinct breach of the law.

7444. As stated in the "Shambles of Science"?—As stated in the "Shambles of Science."

7445. (*Chairman.*) The question that was asked was whether you had been present when any such operation had been done?—My answer to that must be, that I have been present at several experiments at which the anæsthesia was not complete or satisfactory from a humane point of view; and then I must leave it to the Commission to infer whether that is a breach of the law or not; I have not taken it from that point of view.

7446. (*Colonel Lockwood.*) Could you verify the names of the operators?—I can give the names of all the operators.

7447. Where you saw animals which you believed were not under complete or satisfactory anæsthesia?—I can give you an instance.

7448. Can you give us the reference?—That of "A Troublesome Dog."

7449. You give that as one instance?—I give that as one.

7450. Who was the operator?—Dr. T. G. Brodie, assisted by Dr. Alcock.

7451. And have you any other?—All the experiments in Professor Starling's laboratory—that is, all the ex-

* *Journal of Physiology, Vol. XVIII., 1895. "The Intravascular Coagulation produced by Synthesized Colloids," by W. D. Halliburton, M.D., F.R.S., and T. W. Pickering, D.Sc. p. 283.—L. L.-af-H.*

periments performed by Mr. Bayliss, did, in my opinion, give very little guarantee that the animals were insensible, especially the one of which an account is given under the title of "The Struggling Cat."

7452. Who performed that operation?—Dr. Bayliss, in Professor Starling's laboratory.

7453. In "A Long Experiment," is that one you witnessed yourself?—Yes, all these I witnessed myself.

7454. And in all those, or most of them, you believe that the animal was sensible to pain of some sort?—More or less. I believe, to make a general statement, that the anæsthesia was not satisfactory from the humane point of view. And there were certain circumstances connected with the experiments which led me to infer that—notably, in some cases the omission of the constant renewal of the anæsthetic, which always has to be done; and in other cases the admission of the lecturer or demonstrator that morphia had been given, morphia and a little chloroform; and in other cases the behaviour of the animal, as, for instance, "The Struggling Cat," or "The Troublesome Dog."

7455. May I take it that you object to experiments on living animals altogether (it is only with a view to eliciting your opinion); or that under complete anæsthesia, if you believed the object was necessary to save human life, you would not have objected?—I object on principle to all experiments on living animals, and I do not believe they could be useful in saving life.

7456. You object to all experiments on living animals?—Yes.

7457. Whether anæsthetised or not?—Yes.

7458. As demoralising to the man who operates and to the public who see it?—Yes.

7459. Supposing that the law is continued in some shape or other, could you assist us by any suggestion beyond the suggestion you have made, that opium should never be used as an anæsthetic because you do not think it is one? Could you give us any suggestion as to alterations in the law that would mitigate any sufferings that might happen under the present law?—As a first alteration of the law I should certainly suggest the prohibition of demonstration experiments before students, as being, to my mind, abolition piecemeal, which would take away a very important part of vivisection, and would certainly do very much to help the anti-vivisection cause. Then, though I am not in favour of the exemption of one animal and the leaving out of others, I should say that all experiments on dogs, cats, monkeys, and all the higher animals are especially objectionable, and especially experiments on monkeys. I have a monkey myself, and have personal experience of its extreme intelligence and sensitiveness.

7460. From your experience of what has gone on and what you have read, do you believe it would not be hostile to science if those higher animals were left out?—I think it would be very much objected to by the representatives of science.

7461. That would be another point. Do you believe that it would not be dangerous to science?—I do. I believe that all experiments on living animals could very well be dispensed with by science.

7462. And would you suggest any further safeguarding of animals by way of more inspection?—No, I would not suggest more inspection.

7463. You think that more inspection would be useless?—I think that inspection would perpetuate the practice.

7464. Therefore the addition of inspectors, or surprise visits, or more numerous inspections, would all be useless from your point of view?—Yes. Of course, I think the present inspection an utter failure; but I do not feel justified in saying that I should agree to any steps for further inspection.

7465. It would not help your cause a bit more?—No.

7466. (*Chairman*). When you say that you are against all operations, does that include operations for testing the effect or the safe dose of new drugs on animals?—Yes, it does; it includes all inoculations and testing experiments; because I am convinced, in fact, I know, from having seen the effects of such inoculations at the Pasteur Institute in Paris, what suffering they involve. It is not only the prick of a pin.

7467. (*Sir William Church.*) Would you kindly tell me what is the date of, I think it was Dr. Halliburton's textbook, which you referred to in connection with your "Dog Injection with a Substance Derived from a Lunatic"?—I referred just now to the "Journal of Physiology." I did not refer to any text book.

Miss L. Lind-af. Hageby.

1 May 1907.

7468. I think you quoted Dr. Halliburton as proving that very little was known with regard to the action of choline?—I will give the exact words.

7469. I only want the date of the book?—It is the seventh edition of Professor Halliburton's "Handbook of Physiology," formerly Kirkes' "Physiology," published in 1905.

7470. That is the edition you quoted from?—Yes.

7471. That is what I wanted to know. Thank you?—I have found the quotation. It is page 177.

7472. I do not think I need trouble you to read it again. I think you thought that his experiments which he had performed on cholin were of no practical value at all?—I quoted his own words to show that he himself found so.

7473. I do not think he quite says that?—He says: "It is possible that such tests may be of diagnostic value in the distinction between organic and so-called functional diseases of the nervous system"; and I quoted that experiment as one that could not properly be defined as absolutely necessary, because, for one thing, it has no therapeutic value, its diagnostic value is doubtful, according to Professor Halliburton himself, and its physiological value is not absolute, because on this very page Professor Halliburton himself maintains that cholin could just as well be tested by a purely chemical test. These are his words: "The tests employed to detect cholin are mainly two: (1) A chemical test, namely, the obtaining of the characteristic yellow octahedral crystals of the platinum double salt from the alcoholic extract of the cerebro-spinal fluid of blood; (2) a physiological test, namely, the lowering of arterial blood-pressure (partly cardiac in origin, and partly due to dilatation of peripheral vessels), which a saline solution of the residue of the alcoholic extract produces."

7474. (*Chairman.*) When you said "absolutely necessary" just now, you meant for the purposes of demonstration?—Yes, that was my first point.

7475. (*Sir John McFadyean.*) I thought you said a minute ago that Professor Halliburton himself alleged that these tests were of equal value? That does not follow from what you read; they might both be tests, and one might be useful in certain circumstances, and the other might not, and one might be better than the other?—He does not say anything about it.

7476. But I think you used language which implied that Professor Halliburton said that they were of equal value; that one could be used in place of the other?—The words of Professor Halliburton imply that they are of equal value. He says there are two ways of testing cholin, (1) and (2); and I maintain that when there is a chemical test which would be equally useful, it is not necessary to include the physiological demonstration.

7477. (*Sir William Church.*) This lecture that you attended was at the University of London?—This particular lecture was at the University of London.

7478. But it was for advanced students, was it not, not for ordinary medical students?—It was for ordinary medical students; all the medical students from the London School of Medicine for Women who wanted to go to these lectures could go. Any medical student can attend them. They are called advanced classes.

7479. They have to apply for admission?—Yes, you have to apply. I think any student under the University of London is allowed to go. We applied for tickets from the Principal of the London University.

7480. (*Colonel Lockwood.*) What is the course called?—It is called "Advanced courses of physiology, open to all students within the University of London."

7481. (*Sir William Church.*) But it is an advanced course for students?—Yes, it is called an advanced course.

7482. Would you look at page 76 of your book. You say: "The lecturer tells us that the animal is anæsthetised with morphia and some chloroform, and adds: 'These unusual circumstances under which the experiment is performed will perhaps interfere with

Miss L. Lind-af-Hageby.

1 May 1907.

the results.'" Was it the morphia and chloroform which constituted the unusual circumstances? What do you imply by that?—We imply simply the question. We ask whether Professor Halliburton meant that the unusual circumstances were the chloroform and morphia. We imply nothing more than the question.

7483. Then why do you put in the book: "Was it the morphia and chloroform which constituted the unusual circumstances'?—That is just what we did not know. That is why we put it as a question. We did not put it as a statement; we put it as a question.

7484. (*Sir Mackenzie Chalmers.*) A question with a meaning attached to it, though?—Perhaps.

7485. (*Colonel Lockwood.*) That is the experiment with a substance derived from a lunatic?—Yes.

7486. (*Sir William Church.*) Did you not gather that it was an experiment which he thought was better performed under morphia and chloroform than under A.C.E., or chloroform alone?—The lecturer said nothing about it. He told us that it was performed under morphia and chloroform, but he gave no reasons why he had chosen those two drugs.

7487. (*Sir Mackenzie Chalmers.*) Might not the quotation have this meaning: that it was unusual for him to give both morphin and chloroform, as he usually only gave chloroform or the A.C.E. mixture?—It might mean that. Of course, I cannot commit myself to say what he meant. It is merely put as a question.

7488. But still it might mean that?—It might. It might also mean that on other occasions only morphia was used.

7489. And if what I suggest was his explanation, should you accept it?—Yes, I think I should accept it.

7490. (*Sir William Church.*) You know that experimentation with cholin is a new thing; the action of cholin has only lately been found out?—Yes.

7491. That you were aware of when you went to the lecture?—But I think that things which are just found out should not be tried before students immediately.

7492. I am not speaking of students; but you were aware of that?—Yes, that was just why I urged that it is not a necessary experiment, because it was so new.

7493. But you do not suggest that this demonstration is one which would be performed before ordinary medical students?—Yes, the medical students who attended those lectures were ordinary students.

7494. You make no difference between an ordinary medical student who has to attend a certain number of physiological lectures and an advanced student?—No, I think any medical student had the right to attend those lectures.

7495. The demonstration was given specially, was it not, to advanced students; it was headed "Demonstration for Advanced Students"?—When we came to attend these lectures, the conditions were these: There were placards in the London School of Medicine for Women that these courses were given in various places, saying where you could obtain tickets, and anybody who applied was admitted. We applied in that way, and got our tickets, and were admitted.

7496. The chemical test that you have alluded to is a difficult one, is it not?—I have never seen the chemical test. I should not think it is more difficult than many others.

7497. The physiological test is more easily obtained—the effect of cholin on blood-pressure?—I do not know whether it is more easy to try it on a live dog than to try it in a chemical test tube. I should say that the chemical test tube ought to be nearer at hand.

7498. Are you aware whether it has been found that, as the result of the researches that have led to the discovery of cholin and its action, it has ever been used practically or not?—I believe that the discovery of cholin has a certain practical value in the treatment of nervous disease, but I am unable to see that the injection of cholin into live dogs is of any value whatever, because it has no therapeutic value; it is merely a product of disease.

7499. Was not the object of the experiment to show the action of cholin upon blood pressure?—Yes.

7500. And has it been found already of much use, as Dr. Halliburton says it may be found? I wanted to know whether you were acquainted with any of the investigations which have been made in it from a practical point of view?—No, I am not acquainted with any use that has been derived out of experiments on dogs with cholin.

7501. You are not aware that it has been already used to distinguish between cases in which there is nerve degeneration, and cases in which no degeneration is present?—That I am quite aware of. That is why I said a minute ago that the discovery of cholin would undoubtedly be of great value as a means of distinguishing between various different diseases. But I say again that that does not touch the point of injecting this product of disease into a live dog. That has no value whatever, so far as I can see.

7502. How are you to investigate it and find out what the effect of cholin is and whether it is prevalent in the blood of the patient, unless by experiment?—By the chemical test which Professor Halliburton refers to as one method.

7503. The chemical test is a more difficult one?—I do not think it matters if it is more difficult; chemical experiments are generally difficult. I do not think it is more difficult than others.

7504. Your impression was that the animal was not fully anæsthetised in the case which you describe?—I do not think we make any suggestion that the animal was under insufficient anæsthesia. The suggestion is made that the animal was killed in a very inconsiderate way.

7505. I should like to ask you a question or two about how it was killed afterwards. But I drew myself, perhaps quite incorrectly, the inference from your question at page 76: "Was it the morphia and chloroform which constituted 'the unusual circumstances'"? that you were rather under the impression that morphia having been used, the dog was not under full anæsthesia?—The inference there is whether the use of morphia and chloroform constituted unusual circumstances. The inference seems rather to be what are the usual circumstances, what happened on other occasions.

7506. Then you do not doubt that this dog was under complete anæsthesia?—I cannot say that we were satisfied, but there was nothing special during that demonstration to suggest any bad form of light anæsthesia.

7507. You thought that the method of killing was improper?—The method of killing is really what is mostly criticised in this chapter besides the nature of the experiment—that the assisting demonstrator did not even take the trouble to see that the animal was really dead.

7508. But surely he did. Would you tell us what happened?—It was exactly as it is described in this book.

7509. (*Sir Mackenzie Chalmers.*) Would you describe it in your own language?—The demonstrator attached a glass tube to the opened jugular vein, and first we were told that the animal was to be killed. Then he blew a little air into the jugular vein and then sat down, so far as I remember, among the audience, and the lecture went on, and the animal was supposed to be dead; but after a minute or two the dog began to struggle and to show signs that it was not dead, and for some time nobody observed it.

7510. (*Sir William Church.*) In what way did it show signs that it was not dead?—By struggling. "It has begun to struggle, and seems to be in great pain." "At last the lecturer happens to look at the 'dead' dog. He says something to the assistant demonstrator, who leisurely rises from his seat and strolls up to the animal." The suggestion there is rather that the assistant demonstrator ought to have got very upset over his bad killing, and should have rushed to the animal and killed it quickly.

7511. (*Chairman.*) You said in your book "strolls" to the animal?—Yes.

7512. You say now that he "rushed"?—The suggestion we make is that he should have been in a greater hurry than he was.

7513. (*Sir William Church.*) You know that blowing air into the vein is a way of killing animals?—Yes, I know that; I have seen it stated somewhere that it has

to be done very carefully—that different animals require a different amount of air.

7514. You do not suggest that blowing air into its veins enabled this animal to feel pain?—No, not that in itself.

7515. It was really that the assistant demonstrator was not successful in his first blow?—And also that he did not care sufficiently that he was not successful; that when the animal struggled his attention was not so directed towards the animal—that he did not notice it at first, but it took some time, and that that implied a certain amount of carelessness.

7516. How long a time elapsed between these two blows, do you think—the first blow and the second?—That I could not possibly say at this time; it may have been three minutes, it may have been four; it may have been five minutes.

7517. You do not remember?—I could not remember now.

7518. Would it be five minutes?—At the utmost five minutes, I should say. It may have been three or four minutes.

7519. Do you think that the struggling of the little dog indicated that it was coming out of its anæsthesia?—Yes, I think it did.

7520. That is why you think it was careless that it was not watched?—Yes, the whole attitude of the lecturer and the demonstrator I think indicated carelessness.

7521. You are quite sure that these struggles did not follow the second blow of air into the veins, that they were before?—They were before.

7522. Did any follow the air being blown into the veins?—They followed the first blowing into the veins.

7523. But the second?—We do not say that he blew in air a second time. That it is not said. It is said that he resorted to his scalpel. I do not think there is anything said about a second blowing in of air.

(*Chairman.*) No, you say that the scalpel was used?

7524. (*Sir William Church.*) What I asked was when the struggles took place; whether they took place before or after the second blowing of air into the veins?—They took place after the first blowing; there was no second blowing, so they could not take place after that. They took place after the first blowing.

7525. (*Sir John MacFadyean.*) But you say that he repeated it?—No. We say "In order to stop any further pranks played by this obstinate life, he resorts to his scalpel."

7526. I beg your pardon; I was reading another passage to you: "He repeats it and then sits down among the audience." I take it that you describe that as one operation; but, nevertheless, you say that he repeated the operation of blowing into the veins?—But that happened before he sat down among the audience. Those were done whilst he was still standing by the dog. I did not count that as two blowings. I understood that the question was whether the demonstrator first blew the air into the animal and then sat down, and then went and blew in air again, and then afterwards resorted to the scalpel.

7527. You count the first two as one?—Yes.

7528. (*Sir William Church.*) I did not understand that before. Are you quite sure that these struggles which you thought meant returning to consciousness, were not the effect of the air being blown into the vein?—I do not know whether the effect of blowing air into the vein is struggling.

7529. You had never seen it done before?—I had never seen it done before, but I have never heard or read anything to that effect.

7530. You are not aware that struggles and convulsions are the way in which death generally takes place in these cases where air is blown into the veins?—Even if it were so it is no proof that the animal may not have been returning to consciousness.

7531. I am not saying whether it is proof of that or not; I suggest that the explanation of the struggles and convulsions may have been the blowing of air into the veins?—I am perfectly sure that in a deeply-anæsthetised animal the introduction of air into the vascular system would not result in struggles.

7532. What makes you perfectly sure?—The general behaviour of an animal that is under deep anæsthesia—the totally limp condition and absence of struggles.

Miss L. Lind-af Hageby.

1 May 1907.

7533. Have you ever worked at the question yourself? I do not know how far you worked in physiology; have you any practical knowledge? You say that you have never before seen air blown into the vein to kill an animal. Now you tell us that you are quite sure that if an animal is properly narcotised or anæsthetised it could not die with struggles and convulsions?—Yes, I am perfectly sure of it.

7534. Have you any reason for that certainty?—I have the reason of my general knowledge of the effects of anæsthesia. I have never seen, of course, for instance, air blown into the vascular system of a human being, but it is my general knowledge of the demeanour of the patient, whether animal or man, under anæsthesia, which makes me believe that if an animal is properly anæsthetised, it does not struggle when air is blown into the jugular vein.

7535. But may not your inference be incorrect; you are only giving us your inference?—Yes.

7536. Can you give us any facts with regard to it?—I daresay I could get some facts with regard to it.

7537. We are told—at least, I have been told; I may have been told incorrectly—that convulsions and struggles are the way that death occurs in these cases where air is blown into the vein, whether the animals are narcotised or not?—Nothing of the sort is said in this case about the animal coming out of the anæsthesia. It is simply said, "It has begun to struggle, and seems to be in great pain."

7538. (*Sir Mackenzie Chalmers.*) "Seems to be in great pain"—that is inconsistent with anæsthesia?—It is.

7539. (*Sir William Collins.*) Have you seen certain observations on the "Shambles of Science," prepared by Dr. Thane, and dated December, 1903, which have been supplied to the Commission?—No, I have not. I shall be exceedingly glad to see them.

7540. (*Chairman.*) You will understand that this was a confidential report made by Dr. Thane to the Home Office after the publication of your book. The confidential document has been handed to us, and you will be examined upon it; and it is simply because questions will be asked upon it that it can be handed to you for your convenience; but it is not handed to you for any purpose of publication?—I quite understand.

7541. (*Sir William Collins.*) I notice, in regard to a matter upon which questions have already been put to you about a dog injected with the substance derived from a lunatic, that Mr. Thane states in this paper: "The lecturer gives the following account of the alleged revival of the dog: 'The animal was fully anæsthetised throughout with morphia and chloroform. After the experiment had been successfully performed, I said we should now kill the animal by one of the most rapid methods available—viz., by blowing air into the dog's veins. The vein already previously exposed for the administration of the drug was used, and air blown in by my assistant in the experiment. The first blow was not, as it usually is, successful, because he omitted to clamp the vein when he stopped blowing, and a good deal of the air came back again. So he gave another blow, this time taking the usual precautions to clamp the vein afterwards. The blood pressure fell to zero, the heart ceased to beat, and the dog ceased breathing. This occurred in a few seconds. My assistant returned to his seat, and I said 'The animal is now dead.'" Have you any remarks to make upon that?—Yes; that would be the two first blowings, and then the assistant sitting down and Professor Halliburton remarking, "The animal is dead." Is there any account of the revival?

7542. Up to that point, you have no exception to take to the statement?—No, I think it is exactly the same as in "Shambles of Science."

7543. Then he proceeds: "The sudden failure of the circulation and respiration produced the usual asphyxial convulsions. These, which are due to either want of blood or presence of excessively venous blood in the nerve centres, especially in the medulla oblongata, do not indicate any return to consciousness. Fearing, however, that the convulsions might alarm

Miss L. Lind-af-Hageby.

1 May 1907.

some members of the class, I asked my assistant to kill the animal, which he did, and so put a final stop to the movements"?—I think that account is exactly the same, though in different terms, as that given in "The Shambles of Science"—the two blowings, the sitting down, and the movements of the dog supposed to be dead.

7544. You notice that he states that the usual asphyxial convulsions do not indicate any return to consciousness?—Yes, I quite expected that answer to be given.

7545. You think it is a matter of opinion rather than a matter of fact?—Yes, I quite expected that answer.

7546. Would you say that asphyxial convulsions are absent where the narcosis of chloroform has been carried out so as to terminate fatally?—I should think so. I have already quoted some evidence on that point, that, inasmuch as anæsthetics are used so much as antispasmodics and to allay convulsions, I believe that such convulsions are incompatible with perfect anæsthesia, deep anæsthesia.

7547. You are not speaking on that from your own experience?—No.

7548. (*Chairman.*) When you say you quite expected that answer from Professor Halliburton, do you mean to imply that it was untrue?—I do not mean to suggest that; but I mean to suggest that the point of view of the vivisector is so different from the point of view of the person who looks upon these experiments from the humane point of view, that you can only expect two totally and entirely divergent opinions; it always will be so.

7549. (*Sir Mackenzie Chalmers.*) You mean that the same phenomena produced two absolutely different views?—Entirely, and they always will.

7550. (*Sir William Collins.*) In the case of No. 13—"A Grand Demonstration," pages 139 to 148 of your book—I see Mr. Thane, referring to that, says: "The 'struggles' are denied altogether." That appears to be a conflict of fact?—That surprises me, because they were so evident that anybody must have seen them, and if they are denied, I should like to ask why so many efforts were made to anæsthetise these three animals. That is the only reason why the operation is recorded this book. They failed—constantly failed, showing the great difficulties accordingly—as the chapter ends by saying: "This was an example of careful, complete, and public vivisectional anæsthesia. What about the careless, incomplete, and private?" We looked upon this demonstration as giving an example of real carefulness, so far as carefulness can be practised.

7551. You say that you saw the struggles?—We saw the struggles as they are described in the chapter, "A grand demonstration."

7552. Then as regards page 142, Mr. Thane says: "The dog, it is known, had been fed by the attendant not very long before; it is untrue that it 'had not been kept long enough within the precincts of the physiological laboratory'"?—But we say in this chapter that this dog had recently come in, according to the statement of Professor Starling, made before the class. "For this experiment it is best to use a dog in a starved condition," says the lecturer. "This one, however, came in only recently, and his pancreatic juice has been secreted in digestion." Professor Starling said that, thereby suggesting that somebody had made a mistake in feeding this dog. In fact, these experiments are always performed after starvation. In Professor Starling's book, "Elements of Human Physiology," there is a phrase in these words: "If a dog be starved for six successive days and be made to do hard work on the last three, then it will be found that there is no difference in the excretion of urea," showing that starvation is sometimes a scientifically necessary preparation for an experiment. So it was in this case, and Professor Starling merely referred to a thing which is quite usual.

7553. Then you deny that it is untrue that it had not been kept long enough within the precincts of the physiological laboratory?—I deny it, and my denial is based on Professor Starling's words, that he complained that it had not been kept long enough.

7554. As regards page 147, Mr. Thane refers to "the miserable white rabbit." He says the "writer omits to state that it was dead"?—May I ask when it was suggested that the rabbit was dead? Surely not during the experiment when the intestinal extract was injected.

7555. The only light thrown by Mr. Thane on it was this: "'The miserable white rabbit,' the writer omits to state that it was dead. At page 145 it was sent out in order that it might be killed by an overdose of ether; and that is what had happened"?—But we do not suggest that the rabbit struggled after it had been carried out. Our description of its struggles is until the moment when it was carried out. Then we say nothing about it until we go out, and we meet the boy carrying the rabbit into the lecture room again, when the rabbit lay quite still. "The little creature lies still on its board." If it be true that it was dead, then I say that there is nothing in the "Shambles of Science" that contradicts that in any way. We say that the animal struggled until it was carried out as described, and then we saw nothing of this rabbit in the laboratory room until we were leaving, when we met the boy carrying in the rabbit again, and then we say: "The little creature lies still on its board, the head is wet, the hairs stick to the skin, the eyes are protruding and look like glass balls."

7556. You think it was superfluous to state that it was dead?—In other words, we met the rabbit in the door as we were going out, and we make that statement there in connection with that particular period, whether it was dead or alive.

7557. (*Sir John MacFadyean.*) You say, "It lies still"?—Yes, if it was dead it would lie still.

7558. You think that is not calculated to lead the reader to believe that it was still alive?—There can be no wicked suggestion there, because the suggestion would be that it was properly anæsthetised. There can be no harm in that statement.

7559. (*Sir William Collins.*) At any rate, you thought it was superfluous to state that it was dead?—We had no opportunity of seeing. The animal was carried in again when we were going out, and we saw that it was lying still—which shows how accurately we observed it if it was really dead.

7560. Then on page 9 of his report, Mr. Thane, referring generally to your work, says: "Two suggestions run through this work, expressed either openly or by implication. One is that the animals are not properly anæsthetised. This, in the only case in which it has been possible to test the question, has been proved emphatically to be untrue. I believe there is no better foundation for the insinuation in the other cases. Of the 13 lectures dealt with, eight took place at the University of London. Dr. Waller, the director of that Laboratory, is, one may say, an expert, probably the first in the country, on the physiology of anæsthetics. He has given much attention to this subject, and for the last two or three years has devoted, I believe, his whole time to the study of the action of anæsthetics on the nervous system." Is there any remark that you wish to make on that passage?—May I say, in answer to that, that I entirely and utterly disagree with Mr. Thane there; that in the case of the brown dog, to which he presumably refers, it was proved that the anæsthesia had been satisfactory; and, secondly, as the brown dog has been brought in so much before the Commission, I should like to be allowed to make a statement in answer to what I have seen in the printed evidence of Mr. Thane.

7561. (*Chairman.*) You refer to the evidence given before the Commission?—Yes, evidence given before the Commission.

7562. You can refer to anything which has been already put before us by a witness.

7563. (*Sir Mackenzie Chalmers.*) Was the brown dog the case in Bayliss *v.* Coleridge?—Yes.

7564. The jury heard your evidence on that case, did they not?—Yes, they heard my evidence.

7565. And they did not agree with your conclusion?—No, they did not.

7566. (*Chairman.*) You are not going to read your evidence given at the trial?—No, not at all.

(*Sir Mackenzie Chalmers.*) It is the same case?

(*Chairman.*) It is the same case, but the evidence will be on facts which have been brought before us.

(*Sir William Collins.*) And it is dealt with in the paper by Mr. Thane.

(*Witness.*) I have not put down a single word in the statement I have here in connection with the trial on the brown dog which is not absolutely essential to my answer to the statements which have been made by Mr. Thane and Professor Starling concerning that brown dog, and I therefore ask permission to give the statement.

7567. Will you proceed?—I now come to the evidence which I wish to give in immediate connection with the "Shambles of Science," and with special reference to the statements which have been made before this Commission. The book was published July 10th, 1903, by Mr. Ernest Bell. During a period of barely four months there were more than 200 reviews and notices in daily papers and journals of various kinds, and the book attracted a great deal of attention. Had the book been libellous, this period afforded ample opportunity for action. Previous to the publication of the book, Mr. Stephen Coleridge had asked us to give him a statement describing a certain demonstration at which we had been present. This was in illustration of a lecture by Dr. W. M. Bayliss at University College, on February 2nd, 1903.

7568. (*Chairman.*) Is not this going into the case at the trial?—No, it is not; it is only going into the case of the trial so far as it has been brought before the Commission. Certain facts have been stated by Mr. Thane that the book had been withdrawn.

7569. (*Sir William Collins.*) Which answers of Mr. Thane are you referring to?—The brown dog has been brought up before the Commission, I believe, two or three times, if not four times, already. It begins at Questions 1261 to 1283, including 1282.

7570. I see at Question 1261 Mr. Thane refers to a report which he made to the Home Office, for which he was thanked?—Yes.

7571. That is the same report from which I have been reading extracts to you?—That brown dog has been brought before the Commission in answer to Question 1551, and there are a great many questions up to No. 1569.

7572. (*Chairman.*) I am quite aware that it has been referred to, but I do not quite see how your repeating the statement that you made to Mr. Coleridge has anything to do with it?—It is essential that I should mention it, because I wish to prove that there was no connection between the trial and the book. The book was not libellous. It has been stated that the book was withdrawn. Mr. Thane said at Question 1276: "May I add that the 'Shambles of Science' has been withdrawn from publication?" (*Dr. Wilson.*) Only a particular chapter, I think? (A.) No, the whole book is withdrawn, I believe. (*Dr. Gaskell.*) I was told yesterday that a new edition had just come out, and was seen in a shop? (A.) Then that is quite relevant. But I should like to look at the letters that were sent in; because my recollection is that a letter was sent from the publishers saying that it was withdrawn." Then follows the whole letter, in which Mr. Bell promised to withdraw the book. As that has been brought before the Commission, I thought I might be allowed in a few words to refer to it, and to show fully and accurately what occurred.

7573. (*Sir Mackenzie Chalmers.*) Yes?—It is not very long; it is a very short account.

7574. (*Chairman.*) Well, we will see?—This was in illustration of a lecture by Dr. W. M. Bayliss at University College, on February 2nd, 1903. The animal experimented upon was a brown dog, which attracted our attention in a special way because it bore marks of previous vivisections, and because of its movements upon the operating board. It was afterwards admitted that we had been present at the third vivisection of this dog, and that the animal had moved, though the movements were declared by Mr. Bayliss and Mr. Starling to be due to a special disease and not to consciousness. Mr. Coleridge read the statement which we had given to him at a large meeting in St. James's Hall in May, and as a result of this Mr. Bayliss instituted proceedings for libel. During the trial, which took place in November, 1903, the connection between that statement and the chapter "Fun," in the "Shambles of Science," became established, and in consequence of this Messrs. Hempson, solicitors to Mr. Bayliss, threatened Mr. Bell with legal proceedings unless he signed an undertaking to withdraw all copies from circulation, and not to print or publish any further copies. Without committing myself to any criticism of Mr. Bell's action, I wish to point out that we gave no undertaking to withdraw the book from circulation, that we in no way concurred in Mr. Bell's decision, and that the rest of the chapters of the book could in no way be affected by the result of the Bayliss *v.* Coleridge trial. This, our opinion, was strengthened by a remark made by the Lord Chief Justice during the trial. He said, referring to the "Shambles of Science": "This book is not libellous."

Miss L. Lind-af-Hageby.

1 May 1907.

7575. I have never found any report of that taken by itself. Do you mean to say that he said there was nothing in the book that was libellous?—He said, referring to the "Shambles of Science": "This book is not libellous."

7576. Has that been reported?—It has not been reported, but at the time there were so many people who had heard the statement that a special list was circulated and signed by a number of people who had heard it. The reason why it was omitted from the report I do not know.

7577. I am quite sure it was never said.

(*Secretary.*) It is not in the transcript.

7578. (*Chairman.*) I am quite sure that the Lord Chief Justice never said it?—I know that he said it.

7579. If he said it, he said it with qualifications, and in a context which could not give it the meaning which you are giving it now?—He absolutely said those words. I have brought with me the list signed by a number of people who heard it.

7580. I do not care if a thousand people signed it; I should say that it had not got his authority. I am quite sure that the Lord Chief Justice never would confirm it?—I am sure that he said it.

7581. He says in the course of the trial that it is an undoubted libel to speak of a person having committed an illegal act?—He could not say that, because the book itself is not libellous, and cannot be libellous, because no names are mentioned. How could it be libellous when no names are mentioned?

7582. You do not understand enough law, I am afraid, to know that it is not necessary to mention persons' names to constitute a libel?—May I just say that had the book been libellous there was plenty of time to institute actions of libel against us. The book was out for four months.

7583. We are not here to try the question whether the book is libellous or not. What you are entitled to say is that inasmuch as it is made a point against you that you have withdrawn your statements because Mr. Bell withdrew that chapter from the book, that was not done by your wish or authority?—That is all I beg leave to say.

7584. You must confine yourself to that?—I am obliged to answer your questions, my Lord. I did not start this.

7585. You read a long statement?—I am only answering the statements that have been made. If there is anything which goes beyond that in this statement, I shall at once stop reading; but to the best of my belief I have not put anything in which is not absolutely necessary in answer to the statements that have been made.

7586. All I wish you to do is to confine yourself simply to that point. I quite understand that you say that the withdrawal of that chapter was a thing with which you had nothing to do, and which you never authorised?—Shortly after the withdrawal of the book an address of confidence was presented to us ——

7587. This is going beyond?—This is just to show how the book came out again.

7588. We must proceed on some regular system?—May I just put this to you? It has been said that the book has been withdrawn, in other words, that the book does not exist any more because it was a libellous production.

7589. We know that the book has been printed since —that a new edition has been printed with your authority?—That is all I wish to get clear.

7590. We have got all that before us?—May I now proceed with my direct answer? Professor Starling has said in his evidence, at No. 3545, that we gained admission to the London School of Medicine for

Miss L. Lind-af Hageby.

1 May 1907.

Women by stating that we "wished to take up medicine as a serious pursuit." This is untrue and manifestly absurd; for, as Professor Starling should know, one cannot study medicine by merely taking up the subject of physiology, and we made no application for any all-round medical training. Mr. Thane has told this Commission that we have misrepresented the question of anæsthesia in our book. I beg to submit that we have stated nothing which is not amply borne out by other records and experiences of vivisectional anæsthesia, some instances of which I have laid before the Commission. Out of 12 chapters which contain descriptions of various experiments, two record attempts to produce satisfactory anæsthesia; three describe experiments under morphia and a little chloroform, which took place at the Physiological Laboratory, University of London. Of these animals, one is described as being quiet, and one as giving a good deal of trouble by struggling and whining, the third as struggling after it was supposed to have been killed by air blown into the jugular vein. The descriptions of three other experiments which took place at Professor Starling's laboratory, University College, contain no such record, for the lecturer, Mr. Bayliss, gave the students no instructions as to the existence or conditions of anæsthesia. During the trial of Bayliss *v.* Coleridge, he admitted that it was not his practice to tell the students about the methods of anæsthetising the animals (2nd day, 354). During one of those demonstrations, that described under the title "The Dog that Escaped," Mr. Bayliss stated that the animal was slightly curarised. Professor Starling has already answered questions on this chapter, and I must point out that he grossly misquoted it, and then characterised his own misquotation as "wilful deception."

7591. (*Sir William Collins.*) What is the number of the question?—4278. These are his words:—"The writers say: 'If the dog was under curare, if it had artificial respiration.'" Whereas anyone who takes the trouble to read the chapter can see that we did not use the suggestive "if" in either case, but, on the contrary, stated definitely, on the authority of Mr. Bayliss himself, that the dog had had a dose of curare, and, according to our own observation, that no artificial respiration had been established which was the cause of the early death of this particular victim.

7592. What is the page of your book?—That is called "The Dog that Escaped," page 67 in the first edition.

7593. Where are the references to "If the dog was under curare," which you say Professor Starling misquotes?—Professor Starling says that we said, "if the dog was under curare."

7594. What is the page in your book?—There is no such page; that is just my point. He entirely misquotes it.

7595. You mean that it does not occur in your book? —Yes.

7596. (*Sir Mackenzie Chalmers.*) That he has imagined the quotation?—Yes.

7597. (*Chairman.*) You say that he is misquoting some particular passage; what is the passage?—This is the passage, on page 68: "He struggles as much as he can till the lecturer injects something into the jugular vein; a peculiar stillness follows. 'The animal is now slightly curarised,' says the demonstrator; 'we want to excite the sympathetic and the vagus end.'" We do not say "if it was under curare," "if it had artificial respiration"; but we state definitely, on the authority of Mr. Bayliss, that the dog had had a dose of curare, and, according to our own observation, that no artificial respiration had been established. That is why I say that Professor Starling has misquoted the chapter. One experiment was performed under conditions which led us to infer that the animal had been curarised, although nothing had been said by the lecturer about anæsthetics or curare. Shall I give the reference to that?

7598. (*Sir Mackenzie Chalmers.*) I think it would be convenient if you would?—It is the chapter called "The only completely satisfactory method," page 129 of the old edition. This inference was based on Dr. Brodie's own words in his book "Essentials of Experimental Physiology," to which I have already referred, and his preference for curare which is expressed therein. One description, entitled "Painless Experiments," deals with the common experiments on frogs, for which anæsthetics are out of the question. Of the two remaining, one was performed, according to the lecturers, under morphia and scarcely any anæsthetic, and the other under morphia alone. Mr. Thane has given as his opinion to the Commission that there is no foundation for our statement that "very often vivisection is received like a kind of entertainment; there is laughter and merriment, and nearly always there is evidence that most of the students find the proceedings exceedingly 'exciting.'" I fear Mr. Thane can never have been present at any of these demonstrations, and at any rate that the 28 experiments out of the total of 19,084 which were witnessed by him in 1903 did not include any of those described in the "Shambles of Science." Medical students are not notorious for dignified seriousness, and though I have no intention of suggesting that the infliction of pain and suffering would in itself give rise to merriment, I think the general taste for fun and rowdyism in medical students is sufficiently well known to justify the sentence quoted. In 1884 the "Medical Times" referred to the London medical student as "a little wild, a little rough, and guilty perhaps of occasional lapses from virtue." Though I believe much improvement may be found in the present-day students, there is certainly still room for more virtue. Our experience that the students find the proceedings exceedingly exciting has been shared by many, as for instance the late Professor Bigelow, Professor of Surgery in Harvard University, who said: "Watch the students at a vivisection. It is the blood and suffering, not the science, that rivets their breathless attention." And the late Sir Benjamin Ward Richardson, who said about demonstrations before students: "Intellectually, I do not think my classes were assisted, in the main, by the experimental demonstration. I am sure it limited my sphere of usefulness, by leading me, in the limited space of time at my command, to omit some parts of physiology of a simpler, less controversial, and more useful kind. I am bound to say, too, that, morally, I did not recall the effect as produced all that could be wished" ("Biological Experimentation," p. 144). A statement occurring on page 152 (first edition) of the book was put to Mr. Thane, and considered by him to be a misrepresentation. The statement is the following: "In the pain-tortured bodies, trembling under the sharp steel bathing in their own blood, and in vain trying to tear the straps that fasten them to their crosses of agony, twitching under the piercing currents of artificial electricity, there is no trace left of the normal life in the nerves, in the blood, in the wonderful co-ordinated mechanism of the internal organs." This passage should be read and quoted in connection with the following: "Or, when the nervous system, with its myriads of delicate cells, the powers and innermost functions of which offer such insolvable mysteries to our outer senses, is injured by curare, morphia, ether or chloroform, how can we under such conditions get the faintest idea of their true nature?" For these two paragraphs were written to show that pain and anæsthesia are equally unsatisfactory physiological conditions, an assertion which the recent attempts of physiologists, notably of Professor Pawlow's school, at producing normal conditions fully bear out. In the work by Professor Pawlow, which I have quoted before, there are such opinions expressed which entirely tally with the opinions expressed in these two pages in the "Shambles of Science." Professor Pawlow says on p. 15 in his book "The Work of the Digestive Glands" (in dealing with operative technique in animal experimentation): "Such a discussion of operative methods appears to me necessary, chiefly because it becomes more evident every day that in the ordinary method of the so-called 'acute' experiment carried out at one sitting, and complicated by free bleeding, many sources of error lie concealed. The crude damage done to the integrity of the organism sets up a number of inhibitory influences which react upon the functions of its different parts. The body as a whole, in which an enormous number of different organs are linked together in the most delicate fashion for the performance of a common and purposive work, cannot in the nature of things remain indifferent to forces calculated to destroy it."

7599. (*Sir William Collins.*) On that point with regard to anæsthesia which you have just mentioned, I do not think you have disputed in your evidence that you regard chloroform as a true anæsthetic?—I regard chloroform as a true anæsthetic if used in the proper way.

7600. Both in men and in dogs?—Yes.

7601. In the lower animals generally?—Yes.

7602. Although you have some doubt as to morphia,

you consider that chloroform may be regarded as a true anæsthetic?—I do not consider morphia an anæsthetic at all.

7603. You regard it as a narcotic?—Yes.

7604. Would you say that narcosis would be an improper term to apply to the conditions of a patient under chloroform?—The two terms are frequently mixed in a very unfortunate way; people often mix the two terms and use "narcosis" when "anæsthesia" should be used.

7605. I am sure that you are well able to give us a good definition of each?—I should say that the difference between narcosis and anæsthesia is that narcosis is an artificial condition of sleep in which pain is abolished to a certain extent but not altogether, whereas anæsthesia is a condition where pain is entirely abolished and consciousness is entirely lost; which is not the case in narcosis—consciousness is not entirely lost then.

7606. Then you include in your definition of narcosis a presumption that sensation is not wholly lost?—Yes.

7607. So that in all your references to narcosis we must read in that presumption?—It is all a matter of words. Narcosis may be pushed perhaps so far that it verges on anæsthesia; but those differences which I have indicated I think hold true and are the real differences.

7608. But when you refer to narcosis or narcotic conditions you imply by that a condition in which pain is not lost?—A condition in which pain is not totally abolished.

7609. Sensation is not lost?—Exactly.

7610. (*Chairman.*) Is not tobacco often called a narcotic?—Yes, but not an anæsthetic.

7611. (*Sir William Church.*) You have just said that, if pushed, narcotics are anæsthetics?—No, I have not admitted that. I have said that the two terms are frequently confused, and that it is thinkable that narcosis may be pushed sufficiently far to approach what we call anæsthesia; but I distinctly see the difference between the two, and I am not prepared to admit that they are identical.

7612. (*Sir William Collins.*) Do you mean that it is not a difference of degree, but a difference of kind?—Yes, it is a difference of kind.

7613. And that the discriminating difference is that in the case of narcosis sensibility to pain is not lost?—Narcosis is induced by drugs which have not the power of producing perfect unconsciousness; it is produced by drugs which have other effects.

7614. I understood when you kindly gave me a definition of narcosis, that you held that it included within it that abolition of sensibility to pain had not taken place?—I said certain pain. I believe I said that pain in narcosis is abolished to a certain extent, but not totally abolished.

7615. But that sensibility to pain in some degree is always present in a condition of narcosis?—Yes.

7616. So that it would not be right to use the term narcosis in speaking of any condition in which sensibility to pain was in any degree retained?—No; but I must add that this would be my definition of the term, because when one reads the literature on the subject one frequently finds the terms confused. People often talk about narcosis by chloroform and narcosis by ether; and according to the definition which I have just given, that use of the term would be inadmissible.

7617. I was rather anxious to know what you meant when you used the term narcosis?—I can only tell you what I believe.

7618. At any rate, you agree that chloroform and possibly other substances are anæsthetics; I suppose ether would fall in the same class?—Yes.

7619. It is possible to abolish entirely sensibility to pain both in man and in lower animals?—Yes, I quite agree.

7620. Presuming that a vivisectional experiment was carried out under chloroform or ether or one of those true anæsthetics and under conditions in which the anæsthetic was faithfully and continuously applied throughout the experiment, what moral or ethical principle in your opinion would be violated by such experiment?—In the first place, I do not believe that vivisectional operations generally can be carried out under deep surgical anæsthesia, for the reasons I have already stated in my evidence; there are scientific objections, of which I have given instances. Secondly, my moral objection to vivisection is the whole principle of exploiting the lower animals for our supposed service and for our use. I take my stand as an opponent of vivisection rather on that ground than solely and entirely on the ground of pain.

7621. Then your answer, I understand, is twofold. The chief head of your objection is to the exploiting of the lower animals in the interests of man?—The two answers to your question will go together.

7622. I thought you stated that the latter was the more important?—I said that I did not believe but I knew, that vivisectional operations frequently required conditions which cannot be described as perfect surgical anæsthesia; and of that I have given instances to the Commission. And then I said in answer to your question whether I should object to an experiment on a living animal supposing it was unconscious, that I should object to it all the same; because I take my stand against vivisection not only and entirely on the ground of pain, but on the broader humanitarian ground of objecting to the general exploitation of animals for our use.

7623. Do you doubt that operations under what you call surgical anæsthesia are painless?—No; in some cases consciousness may return, but I could not go so far as to say that it frequently or often happens.

7624. That is to say, in a vast number of cases of surgical operations under what you call surgical anæsthesia, the operation is painless?—Yes.

7625. Then I understand that you simply do not believe those who state that vivisectional experiments on animals can equally be carried out under anæsthesia?—I cannot believe it, because I have facts to the contrary based on all the literature on the subject.

7626. (*Sir John MacFadyean.*) You have already made it perfectly plain in answer to previous questions, that you are absolutely opposed to experimentation upon animals in any shape or form?—I have.

7627. I should like to ask whether you are ready to admit, or on the contrary would deny, that anything useful for the cure or prevention of human or animal disease has ever been discovered in that way?—That is a question which it is very difficult to answer; it is all a matter of relative terms. What one considers useful another person might not consider useful. Personally, I believe that the abolition of vivisection will be accompanied by great changes and great development in the whole science of medicine; that new methods of healing will come in, and higher methods, as we know that the coarser medication and the coarser drugging are going out of fashion. From my own point of view, I am prepared to say that nothing which I should call useful has been obtained by experiments on the lower animals.

7628. Do you yourself attach great importance to your own opinion on the question of therapeutics?—I do not attach more importance to my own opinion than the average person does to his. When I am asked for my opinion I can but give it.

7629. I mean as compared with the average specialist on these subjects?—If you ask my opinion as a lay person, I give you my opinion as a lay person.

7630. That is just what I wanted to know; whether you offer it as a lay person?—Yes, I offer it as a lay person.

7631. I really did not know that, or I should not have asked you the question at all. But I will ask you to assume as a fact supported by an immense body of evidence, that discoveries which are valuable for the cure and prevention of human and animal diseases have been made by experimentation on the lower animals; and then I want to ask you this other question: Do you think it right to continue to take advantage of those useful discoveries?—First of all, I do not admit—I cannot admit—as I said, based on my previous answer, I cannot assume, that such inestimable advantages have been gained.

7632. You must not read more into the question than I said. I did not say inestimable advantages?—I beg your pardon: I did not mean to do so.

Miss L. Lind-af Hageby.

1 May 1907.

7633. I did not say whether large or small; I asked you to assume, which does not mean that you are to assent to it. I assume from what you told me before that your knowledge is not wide enough to entitle you to form an opinion; but it is reasonable to ask you to assume that there is a great deal of evidence which many people accept as proving that useful discoveries have been made, and I wanted to know—it is an ethical question bearing on the justifiability of experimentation—whether you think it is right that we should continue to make use of these discoveries in practical medicine. I ask you to assume that for the sake of argument?—Assuming for the sake of argument that such advantages have been derived by vivisectional experiments, personally I should never make use of anything which I consciously knew had been derived by such means.

7634. I will ask you to assume as one of these useful discoveries, the discovery, for instance, of tuberculin, which many people think is calculated to play a very useful part in exterminating or reducing tuberculosis among the lower animals. Do you really think it is immoral on the part of farmers to employ tuberculin, or would you actually discountenance it; would you be opposed to the Government compelling the use of tuberculin, for instance, as a means of suppressing tuberculosis?—Tuberculin is one of the lasting monuments to the failure of drugs obtained through experiments on living animals. The terrible Koch fiasco a few years ago——

7635. You misunderstand me?—No; may I finish? When tuberculin was sent out into the world as a remedy for human beings and finally was discarded as a remedy, it was a great fiasco.

7636. But really I must protest again. I asked you to assume as a matter of argument that the tuberculin was really useful?—I cannot assume that.

7637. I did not wish you to give evidence to the Commission on the value of tuberculin as a diagnostic for tuberculosis?—You chose an instance which was too tempting to leave alone—that was, the fiasco of tuberculin.

7638. Will you forgive me for saying that I do not care in the least for your opinion about the value of tuberculin, but I wanted to know whether, assuming it for the sake of argument to be of great value, you think it would be right to take advantage of it, or whether you would actually deprive farmers of the advantage which they can derive from the systematic use of tuberculin?—Then I cannot assume that with regard to tuberculin without saying that I consider it a great fiasco. It was a great fiasco with human beings, and I do not believe that it is valuable as a test for tuberculosis in cattle.

7639. I am sorry that I am the first person who has put to you a question which has failed to get an answer When you make use of the term "exploiting animals for human use," would you explain very shortly to the Commission what you understand by that expression. Is the keeping of animals in confinement—what we call the domestication of animals—covered by the expression exploitation of animals for human use?—No, it need not be.

7640. Is the killing of animals by methods involving avoidable pain in order that their flesh may be used for human food, exploiting them for human use?—I answer that killing animals for food by methods which involve pain is certainly exploitation of animals.

7641. Are you a vegetarian?—I am a vegetarian.

7642. On that account?—On that account.

7643. You say that you believe that all experiments on animals could be dispensed with, and that science would not suffer on that account?—Yes.

7644. Do you mean by that that up to the present time experimentation on animals has provided nothing of any value whatever—that it is absolutely valueless?—I think I answered that question before. I said that it is a matter of opinion as to what is valuable. To my mind vivisection has produced nothing which is valuable; but I am quite aware that there are other minds to which those results are exceedingly valuable. It is all a matter of comparative values, and I believe that the abolition of vivisection, when these methods are discarded, will be followed by new scientific methods and new scientific light, and that science need not suffer. Science has immense possibilities.

7645. I must put to you one more concrete case referring to a subject about which I know something myself. I believe it to be a fact that a valuable method of immunising animals against cattle plague was discovered within the last ten years—I mean the use of what is called the serum of animals which have recovered from cattle plague or have been hyper-immunised against it. The belief which I hold is shared by, I think, almost everybody who has examined the evidence, or had an opportunity of studying the thing practically. The method has been employed on an immense scale, and is believed to have saved millions of money. Will you tell me whether you think it is in the least likely that that discovery would have been made without experimentation on animals? It involved a great deal of experimentation on animals?—I should not dream of denying that that method has been discovered by experimentation on animals; in fact, that is something that we all know; but the point is whether some other method might not have been employed and could not have been employed with equal advantage. I believe on the whole in natural immunity versus artificial immunity, and I am not at all inclined to admit that the principle is a true or right one.

7646. But when you speak of natural immunity, are you aware that cattle plague was threatening to devastate the whole of the animals in South Africa; there was no time to provide a new breed of cattle with natural immunity. Will you give us some suggestion as to an alternative that might have been used?—I believe that probably there was some cause of that outbreak of cattle plague which could have been avoided. I believe in methods of prevention by sanitation above all.

7647. But it was too late to avoid it; it had been introduced into the country?—I do not know anything of the particular case which you are quoting, but I think that there is enough in the literature of the failure of sera and the whole principle of serum-therapy to warrant very strong opinions against the introduction of unnatural immunity.

7648. That is all the answer that you are prepared to give with regard to that question?—I believe that slaughter and isolation have been proved to be the best remedies in cases like that.

7649. Do you seriously suggest that it would have been better to refrain from attempting to immunise cattle in South Africa, and to have killed them all off?—I have no evidence that the cattle were immunised.

7650. I ask you to assume that, and I think you will not fall into error if you assume that immense numbers were immunised.

EIGHTEENTH DAY.

Wednesday, 8th May 1907.

PRESENT:

The Right Hon. the Viscount SELBY (*Chairman*).

Colonel the Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.D.
Captain C. BIGHAM, C.M.G. (*Secretary*).

Mr. HENRY MORRIS, F.R.C.S., called in; and Examined.

Mr. H. Morris, F.R.C.S. — 8 May 1907.

7651. (*Chairman.*) You are the President of the Royal College of Surgeons of England?—Yes.

7652. And you have been desired by the Council of the College to give evidence before the Commission?—I have been.

7653. The Council, when a letter was read from the Commission, I believe, discussed it, and agreed to a resolution. They discussed it, and agreed to the resolution contained in my précis.

7654. Would you just read us that resolution?—"The Council of the Royal College of Surgeons of England express the opinion that the Act of 1876 is sufficient protection against any abuse of vivisection, and earnestly hope that the progress of surgical science will not be hindered by further restrictive legislation."

7655. You were not present, probably, at the Royal Commission on Vivisection in 1876?—No.

7656. And your evidence is relating to the advance in surgery and to its relation to experiments on living animals since 1876?—Yes. I may say that I have read the evidence of 1876—perhaps not entirely, but very nearly from cover to cover—so that I know the nature of the evidence of 1876. But this evidence of mine is based upon material facts and discoveries which have occurred since 1876.

7657. You propose in your evidence to refer to the advances in surgical knowledge which have been made, or in part made, since 1876 by experiments on animals—(1) As to the scientific and practical conditions essential for the proper healing of wounds; (2) as to the precise causes of many diseases the real nature of which was previously quite unknown to the profession; (3) as to the immunising or curative influence in certain infective diseases of the sera of immunised animals; and (4) as to the importance at the present time of experiments on animals for carrying on research as to the nature and origin of cancer in man and in animals?—Yes.

7658. Experiments on animals in relation to aseptic surgery and the healing of wounds have been of material advantage, in your opinion?—Most material. I quote Lord Lister. We could not have arrived at the knowledge we possess at the present day had it not have been for experiments on animals.

7659. You do not say that that knowledge has arisen from experiments on animals alone?—No.

7660. But there are other modes of investigation which have been going on in research?—Certainly.

7661. Chemical investigations, for instance?—Yes, each of the forms of investigation has been essential, but experiments on animals have been equally, if not more essential or important than the other forms of investigation.

7662. And it is not easy, in your opinion, to separate the advantages which have been derived from each particular source?—It is impossible.

7663. It is your decided opinion as an experienced surgeon that vivisection has been essential?—I have no hesitation in expressing that opinion.

7664. I use the word vivisection, you understand, because everybody uses it. Experiments on animals are not all what we should properly call vivisection, but I use it as meaning experiments on animals?—Yes. Mr. Lister (now Lord Lister), in giving evidence before the Royal Commission in 1876, stated that he could not have made his way in the subject of antiseptics without the assistance he had derived from experiments on the lower animals. It was by means of experiments on animals whilst studying the phenomena of inflammation that Lister ascertained many very important and fundamental facts. Thence he went on to the study of the blood, more especially the coagulation of the blood, thrombosis, etc. The facts ascertained in both these directions formed the basis of his subsequent work on the treatment of wounds. Lister, having come to the conclusion that the disasters which attended wounds were directly dependent on putrefaction of the discharges in the wounds, directed his attention to attempts to prevent this putrefaction, but for a long time without any marked success, because the causes of this putrefaction were unknown. It was after Pasteur had shown that putrefaction, like other fermentations, is caused by microbes growing in putrescible substances, that the problem how to protect wounds from bacteria presented itself to Lister. Lister himself demonstrated in his experiments on lactic fermentation that there must be different kinds of bacteria having different functions. So far, the early beginnings of aseptic surgery were only in part directly associated with experiments on animals.

7665. Pasteur's and Lister's experiments that you speak of were partly on animals?—Yes, both of them were very largely on animals. May I interpose a brief summary of Pasteur's work in three or four lines here?

7666. If you please?—Pasteur's works may be classed in three series—three great discoveries: (1) That each fermentation is produced by the development of a special microbe; (2) that each infectious disease is produced by the development within the organism of a special microbe; and (3) that the microbe of an infectious disease, cultivated under certain detrimental conditions, is attenuated in its pathogenic activity—from the virus it has become a vaccine, and as a vaccine is used for protection and cure.

7667. The important thing for our inquiry is, how far these discoveries were assisted by experiments on animals, and how far experiments were or were not essential?—With regard to (2) and (3) experiments were essential. Pasteur discovered that infectious diseases were produced by different microbes, by experiment.

7668. On animals?—Yes, and it is true that in the first instance it was by an accident he discovered that the microbe of an infectious disease, when cultivated under circumstances which are detrimental to that microbe, converts the microbe and its effect from a virus or poison of the disease into a curative or protective agency against the disease. Those discoveries were made by experiments on animals.

7669. We are not all of us, by any means, skilled

Mr. H. Morris, P.R.C.S. 8 May 1907.

in surgical or medical phraseology. What is the precise meaning of cultivating a bacillus?—Growing it on different media, like potato or broth, and things of that kind, and then producing the bacillus in multiple from the organism which he put upon that material, and also producing the toxins from it.

7670. You mean that the bacillus, as it were, multiplies itself in this new substance?—Yes.

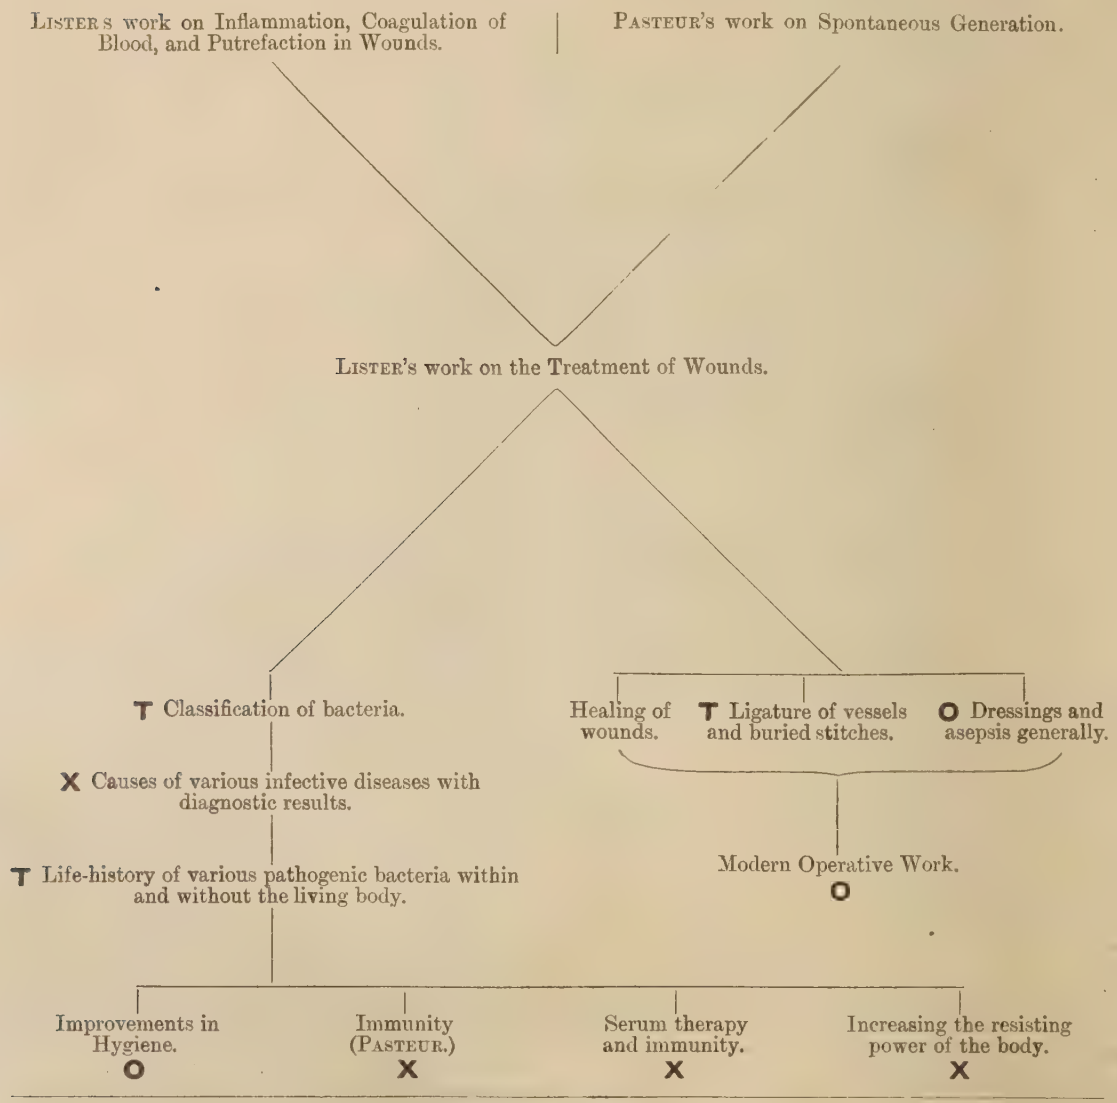
7671. In what way is the bacillus so produced less effective as a poison than the one that is taken out of a living animal?—For instance, this cultivation, if you accept the term now, may be kept for a longer or shorter time, and be impaired in its poisonous effect by being kept; and then when that material is injected into an animal, it does not produce the full poisonous effect upon that animal, but it produces a modified condition, which prevents it from taking the disease.

7672. That is to say, the virus is stronger where the bacillus is found in the blood of a living animal than it is in this cultivated substance or mixture?—When it is fresh. Perhaps I may take the case of the chicken cholera, by way of making what I want to convey clearer. Pasteur found out that the poison of chicken cholera, after it had been kept some considerable time, did not produce the disease when injected into chicken, and that in those chickens which had that old material injected, when submitted to fresh and more active cultures did not develop the disease; whereas other chicken which had not been previously treated with this old culture did develop the disease, and died after being injected with the fresh culture. Does that convey to you what I mean by one of Pasteur's great discoveries? Then, besides that, take, for instance, the tetanus bacillus being taken from a dog which died of tetanus. If that is introduced into other dogs, it produces the disease; but under certain circumstances, which I have mentioned in my *précis*, the poison becomes so weak that it can be injected without producing the virulence of the disease. It is the same with anthrax. The anthrax bacillus has been submitted to various altered conditions by Professor Sclavo and others, and this, when introduced into animals, serves as a means of preventing the disease or of curing it, instead of developing it in its full force.

7673. Then you have a table, which will appear here in your evidence?—If you please.

LISTER'S WORK AND WHAT HAS FOLLOWED FROM IT.

(Drawn for me for the purposes of this Statement by Mr. W. Watson Cheyne, F.R.S., C.B. Member of the Council of the Royal College of Surgeons.)



Lister's work on Inflammation, Coagulation of Blood, and Putrefaction in Wounds.

X

Explanation of Signs.

O Profoundly influenced by knowledge obtained by experiments on animals, especially those leading to the diagnosis and life-history of bacteria.
X = Impossible without experiment on animals.
T = Dependent to a great extent on experiments on animals.

The above "tree" indicates the development of Modern Bacteriology from Lister's work on the treatment of wounds and the relation of the various researches to experiments on animals.

I would say that as the result of the most intense study and work, Lister constantly improved his methods of wound treatment, with the most remarkable results, in the prevention of septic diseases, as well as of certain diseases which at first he had not looked on as due to the entrance of bacteria, such as erysipelas and tetanus; the latter had not previously been thought to be associated with decomposition in wounds. But knowledge of these matters was only increasing slowly and imperfectly till the appearance of Koch's work on the infective diseases of wounds. Koch showed, entirely by experiments on animals, that there are two great classes of bacteria—viz., those that cannot grow in the living tissues—the non-pathogenic bacteria; and those that are able to grow in the living tissues, and growing there produce various forms of disease. Koch further showed that the troubles which arose in connection with wounds might, on the one hand, be due to the absorption of the chemical products of the growth of one or both of these kinds of bacteria in the discharges of the wound; or, on the other hand, to the entrance of pathogenic organisms into the tissues, and their growth in the body. In this way he demonstrated the occurrence of septicemia in mice, due to small bacilli; septicemia in rabbits, due to cocci; pyemia in mice, due to micrococci, and many other things of the same kind.

7674. What exactly is the distinction between a bacillus and a coccus?—A coccus is a small round body, and a bacillus is a rod shape or a dumb-bell shape or a drum-stick shape. They are exceedingly microscopic, of course.

7675. Are these experiments on mice and rabbits applicable to septicemia in man also?—Yes, septicemia in man and the cause of septicemia in man have also been demonstrated and proved accurately by the experiments on mice and rabbits.

7676. What is the connection between discovering septicemia in man and in animals; how is it arrived at by these experiments on animals?—By cultivating the organisms which are found in the discharges or the blood of men suffering from septicemia or pyemia.

7677. Would you not find it in the blood of the men themselves, supposing you made an incision in them?—You may find it there, as has been the case in many diseases in animals. You may find organisms and appearances constantly in the blood or the tissues, but you have not the proof that those are the causes of the diseases until experiments have been made on animals with these materials or organisms, and the same disease has been developed in the animals so inoculated or treated. For instance, if you take the tubercle bacilli found in the tubercle nodules of the human being, and cultivate it, and inject the cultivated material into animals; or even, without cultivating the bacilli outside the body, if you inject the bacilli direct from the urine or from the blood of man, you can prduce tubercle in the animal. But it had to be proved that the disease was due to the bacillus by experiments on animals.

7678. That is to say, you might find that particular bacillus in the blood of a man who had a particular disease, but you could not be sure that that was the cause of the disease without experimenting on animals?—That is so. I was going to say that in that particular disease of tuberculosis, many years before it was identified as being due to the presence of tubercle bacilli, it was known to be an infectious disease, and due to some material in the animal or the person suffering from it.

7679. You go on, in your *précis*, to Koch's work?—Koch established three great things; he laid down three great postulates which have a bearing on this whole subject. These were, that you must find the microbe of the disease, and then, having found it, you cultivate it in appropriate media outside the body and inject it into animals, and then reproduce the same disease over again in those animals so as absolutely to identify the disease with the particular organism by recovering it in the tissues or fluids of the injected animals.

7680. What are the three postulates? You say the third of the three postulates necessitates experiments on animals, but you have not told us what they are?—The first is that you must discover the micro-organism which is the cause of the disease, the coccus or bacteria as the case may be, in every case in which the disease exists. Then, by making a pure culture, separating it from everything else, and making the pure culture of this particular organism, you introduce it into an animal, and it produces the disease there; and then you will find in the blood and tissues of that animal the same organism as you found originally in the individual who was attacked by the disease.

7681. That is the third postulate?—Yes.

7682. The third of these you say necessitates experiments on animals?—Certainly.

7683. I was going to ask, does not the second also? No. Not the cultivation of the organism outside the body.

7684. When you say that experimentation is essential, can you suggest any other means by which it could be done?—No.

7685. Based on these postulates, the discovery was made of the bacteriological origin of a great variety of diseases, both in man and in animals—*e.g.*, tubercle, tetanus, diphtheria, all sorts of wound infections, such as septicemia, pyemia, sapremia, erysipelas, and infective gangrene, as well as gonorrhœa, plague, cholera, pneumonia, and so on.

7686. (*Colonel Lockwood.*) What is sapremia?—It is a blood poison. It is the name given to that form of blood poison where the intensity of the disease and the exhibition of the poison depend upon the amount of the poison; so that, if you have a mild quantity of the poison you get a mild form of the disease, and by increasing it you get an increasing disease. It is known as "septic intoxication."

7687. (*Sir William Collins.*) Is it not a form of blood poisoning that is independent of any micro-organism?—No.

7688. You would not say that?—No, I would not.

7689. (*Chairman.*) The particular bacillus which is responsible for each of those diseases you say has been discovered by experiments on animals?—Yes, and identified and proved to be the cause of the disease.

7690. (*Colonel Lockwood.*) And classified?—Yes, more or less classified into ærobic and non-ærobic, if you understand those terms; and again classified into those organisms where the poison is contained within the body of the micro-organism or is outside the actual body; those where the animal itself causes the disease and those where what is called the toxin or an emanation from the micro-organism causes it.

7691. (*Chairman.*) Tetanus organism, for example, is found in the ground?—Yes, it is one of those that does not live in the air, and is called anærobic therefore, and its poisonous effect is produced by its toxins rather than by the bacillus itself.

7692. When you say that the poisonous effect is caused rather by its toxins than by the bacillus itself, what is the distinction between the bacillus and its toxin?—The bacillus is the organism, but the toxin is some emanation from it.

7693. Is not the way that all bacilli work by their toxin?—No, some of them work by themselves.

7694. Without emitting any toxin?—Yes. As you have asked on this point, I think I could give an illustration, for instance, of the importance of classification of bacteria, and how experiments on animals prove the importance of it in identifying different bacilli in the blood of a diseased animal. Doubts were thrown upon the accuracy of Pasteur's work in reference to anthrax, and certain animals died, which were said to have died from anthrax, but not from septicemia. Pasteur, knowing that the bacillus of anthrax is an ærobic organism, and that the bacillus of septicemia (or using the word blood poisoning in that sense) is an anærobic organism, cultivated from discharges or blood the anthrax bacillus, when exposed to the air, and not the septicemia bacillus, and the septicemia bacillus in an atmosphere of carbonic acid, and not the anthrax bacillus.

7695. What do you mean when you say, "And not the anthrax bacillus"?—From the same fluid he was able to cultivate one bacillus in a culture exposed to the air, namely, the anthrax bacillus, and the other bacillus, namely, the septic vibrio of septicemia, only from a culture exposed to an atmosphere of carbonic acid; and then by taking those separate products of the cultivations he produced the anthrax disease by the one material and the septicemia by the other material,

Mr. H. Morris, F.R.C.S.

8 May 1907.

in different animals. Thus, by the knowledge that the septicemia organism was anærobic and anthrax bacillus was ærobic, he was able to by these different modes of cultivation to get each of these organisms separately from the same blood; and then with each of these organisms separately he produced the corresponding disease in a separate and isolated form.

7696. That is to say, each can only live and multiply in its own element?—Yes.

7697. The ærobic bacillus, you mean, is one that lives in the air?—Yes.

7698. And the anærobic, either in the body or in the ground?—Yes, tetanus, for instance, is an anærobic.

7699. But if it is in the body of a human being?—It will live in the body of a human being—the tetanus bacillus will do that; but outside the body it is existing and persisting in the earth, and in dust, and so on, where it is not exposed to oxygen.

7700. You gave us the particular bacillus that you said was an ærobic bacillus; what was that?—The anthrax bacillus. The septicemia bacillus is an anærobic bacillus.

7701. What is a specimen of an ærobic bacillus?—The septic vibrio of septicemia. I only bring that matter forward to show you the importance of these experiments on animals; that by the introduction of pure cultures of these separate micro-organisms you are able to absolutely identify the nature of the disease of the body from which it is taken, and to produce that same disease again in the animal which is inoculated.

7702. These are experiments in which the only operation consists in inoculating?—Yes, they are inoculating experiments.

7703. With a lancet or syringe?—A syringe.

7704. And any suffering in the animal is a suffering of the disease, really?—Yes.

7705. You go on to speak of the value of experiments as regards improving methods of treatment and prevention?—Yes. Of course, the whole of the aseptic and antiseptic methods of the treatment of wounds is the outcome of this knowledge of the micro-organisms in the putrefective discharges being the cause of the disease. The discovery of the causes of these diseases has led to the early and precise diagnosis of them, and to a more intelligible and effective manner of treatment than was previously possible. In the prevention of the spread of diseases and in hygienic science, advances have been made, owing to experiments on animals, which could not have occurred had such experiments been prohibited. Further, the study of bacteria, and their effects on animals under various conditions, led Pasteur to open up the whole question of immunity. In the course of his experiments on chicken cholera, Pasteur wished to inoculate some fowls, and for this purpose took a cultivation of the bacteria of chicken cholera, which had stood in a flask in his laboratory for some weeks. He found that the animals so inoculated did not acquire the disease as they ought to have done, and on re-inoculation of the same with a fresh cultivation, he further found, to his surprise, that they did not develop the disease; while fresh fowls, which had not been previously subjected to the first injections, did. In other words, he had protected or immunised the fowls by the first inoculation, although they had not shown any symptoms of the disease. This accidental discovery led him to obtain and employ attenuated cultures, which could reproduce the disease in a form having attenuated virulence, and at length a veritable vaccine to completely protect against the virulence of the disease. ("The Life of Pasteur," by Rene Vallery Radot, vol. II., p. 100-1.) These discoveries have proved of great benefit both to animals and human beings, in proof of which it is only necessary to name anthrax, swine erysipelas, and rabies. "Rouget of Swine" (Pasteur's Life, p. 125, vol, II.). The experimental study of pathogenic organisms has also led to the discovery of protective and curative sera of proved value, and of great importance in treating a number of diseases, the most striking instance being diphtheria. The marvellous improvements which have been made since the Royal Commission of 1876 in the treatment of wounds, and in our knowledge (a) of proper disinfection; (b) of the sterilisation of dressings and instruments; (c) of the action of antiseptics on wounds; and (d) of the behaviour of various substances used as ligatures, when buried in the tissues, are due to the precision and clearness with which the nature, the virulence, and the habitats of the various pyogenic organisms have been made out.

7706. When you say buried, do you mean temporarily or permanently buried?—Some of them have been permanently and some temporarily. The old plan of ligaturing was very frequently a disastrous one, because it entailed the application of a silk thread to a vessel, and it was left projecting from the wound. Suppuration was very common in those days, and in the process of separation of the ligature and the ligature coming away, as it was spoken of as doing, secondary hæmorrhage frequently occurred. Improvements were being sought, and various methods were employed, such as a cu-pressure, tortion by many long needles passed in, and twisting the vessels round, to do away with the danger of having these projecting ligatures; and then it went on to the employment, through Lister's experiments, of buried ligatures, using various material, such as ox-aorta gut, cat-gut, and silk.

7707. Which need not be taken out?—Which were tied, and the ends cut short, and left to be surrounded and grown into, or absorbed by the tissues.

7708. I suppose the important thing was that those should be in themselves aseptic?—Absolutely.

7709. And could be absorbed?—Yes, either absorbed or encysted, many of them being absorbed. That was a matter of the very first importance in connection with doing away with the liability of suppuration of wounds and of secondary hæmorrhage. By getting an immediate union, a union by first intention, as we call it, of the wound, these things round the vessels, cut short and left in the tissue, became buried and shut out from all liability of doing harm, which ligatures, hanging tail-like out of the wound, so often caused.

7710. Were these ligatures, which could be safely left in the wound, ascertained by experiments on animals?—Yes.

7711. It was partly the method and partly the materials that was of importance?—Yes.

7712. As regards the materials, would those be employed?—Yes, they were used upon animals in ligaturing the vessels of animals and so on; but also, you see, the connection with experiments on animals in this matter is in the healing of wounds by the discovery of the causes of the suppuration of wounds and the causes of septicemia, pyemia, etc. It all steps together. The experiments led to the knowledge of the preparation of these litagures, as they led to the knowledge of how to get the wound to heal without supperation.

7713. (*Sir William Church.*) The importance of the experimentation on animals was that it demonstrated what were the sources of dangers in these ligatures?—Yes.

7714. (*Chairman.*) All that arose on the question I asked you about the word "buried." Perhaps you will go on about the operations?—I have made it clear that they are simply buried in the wound.

7715. Yes?—Since the danger of septic troubles has been removed, enormous strides have been made in surgery in recent years. Many operations which used to be looked upon as too dangerous to be undertaken, except under stress of necessity or as offering a last chance of saving life, are now performed with absolute safety; many new and important ones, which were formerly never dreamed of, have now become matters of successful and almost daily performance. Finally, whereas the mortality, even after quite simple operations, was at one time so appalling that the patients were often deterred from submitting to, and the surgeon from performing them, operations of considerable magnitude are now undergone with the confidence which comes from knowing that the mortality is, in many instances, but a fraction of an unit per cent. To-day the abdominal cavity of man is opened, every organ within is inspected and palpated for diagnostic as well as for operative purposes, the wound is closed, and the patient recovers from the effect of the anæsthesia, and takes a completely uneventful course towards convalescence. This course is very commonly without pain, without mental shock or distress, without discomfort of any kind beyond some anæsthesia sickness, some flatulence, and the weariness of

lying still. Within 10 or 14 days after such an operation the patient has generally quite recovered.

7716. In what way have experiments on animals assisted to that result?—Through the rapid healing and the healthy condition of the wound from the very start to the finish; whereas, before we knew through experiments on animals what the causes of putrefaction and suppuration were, and how to prevent them, the majority of these wounds suppurated.

7717. You mean Lister's and other's experiments with regard to aseptic treatment?—Quite so.

7718. (*Mr. Tomkinson.*) What does palpated mean?—Handling—taking hold of with your hands—examination by touch, I would rather put it; palpating is feeling with one's hand. You can examine an organ by sight as well as by handling. Or, an incision is made into the loin, the kidney is exposed and freed from its surroundings, is drawn out upon the loin, inspected, palpated, incised and examined by the finger inserted into the wound in the organ, and by a bougie passed down from it to the urinary bladder; the kidney is then replaced, and the patient is well and sitting up in 10 or 12 days afterwards.

7719. (*Chairman.*) We have heard a good deal about operations, not precisely the same, but somewhat of this nature, as regards the laying open of the body in animals. Of course, all those operations, whether upon man or upon animals, are, or should be, under anæsthetics?—Yes.

7720. You have told us what your experience is as to the amount of pain suffered by man. Would the pain suffered by animals under such an operation be, in your opinion, the same or greater or less than that suffered by man?—Allowing that an animal is equally susceptible to pain as man, there would be equally the same immunity from pain and suffering, provided that the aseptic condition after making the wound was kept up.

7721. And provided that in each case the anæsthesia was complete?—Of course, so far as the operation is concerned.

7722. I mean during the operation?—Yes, but not the subsequent course. I am laying emphasis here upon the immunity from subsequent pain—the pain during the recovery from operations, which has been such a remarkable and beneficial result of our knowledge of septic diseases derived from experiments on animals.

7723. Supposing an animal were subjected to an operation (that is, perhaps, hardly the right medical term), which involved cutting into the entrails under anæsthesia, would the animal be treated on recovery in the same way as you would treat a man?—Yes, I believe the Act compels that; I think, I am not quite sure, it compels that they should be treated antiseptically, and if they are treated antiseptically after the performance of the operation, the animal, equally with the man, will recover with practically no suffering.

7724. (*Dr. Gaskell.*) Is it not the fact, or perhaps you do not know, that the recovery would probably be quicker than in man?—I do not know that it is quicker, because really the rapidity with which some of the wounds in the human being heal is so very great that it is almost impossible to be quicker; but probably a great number of wounds upon animals do heal in a shorter time than in man.

7725. (*Chairman.*) I suppose the average constitution of a reasonably healthy animal is better than the average constitution of a human being who is kept alive by so much care very often?—Yes, no doubt.

7726. I think we will not trouble you to read the remainder of your précis, but it will be printed as part of your evidence?—If you please. The *précis* which deals with the subjects classified in the answer to Question 7657 continues:

A joint is the seat of a sudden and most painful inflammation which is mistaken for an attack of acute rheumatic fever; it is nowadays punctured, the fluid is withdrawn and examined, it is found to be septic, and the joint is then at once laid open and drained; immediately all pain vanishes, and the patient quickly recovers with a moveable and natural joint, instead of, as formerly, after a lingering illness if at all, and with a stiff joint, a deformed limb, and suppurating sinuses discharging on the surface of the body.

The disease technically known as osteomyelitis or diffuse abscess within bone is no longer looked upon as due to exposure to cold, or as rheumatic; nor is empyema, or suppuration in the chest cavities, any longer attributed to access of air to the pleural surfaces; but both diseases are alike treated by the freest incisions and drainage, with the result that great suffering is relieved and thousands of lives which formerly would have succumbed to these diseases are saved.

Mr. H. Morris, F.R.C.S.

8 May 1907.

The foregoing are some illustrations of the beneficent results of the combined labours of Lister, Pasteur, and Koch.

Further, I may refer to the recent work of Wright and others on opsonins, which holds out some hope of extending our knowledge as to how to increase the resistance of persons against or how to cure them of such diseases as tubercle, pyorrhœa, and the various diseases caused by staphylococci, such as boils, impetigo, gonorrhœa, etc. Wright has found, and Koch had previously found, that the introduction of the dead bodies of bacteria into animals increases the resistance of the animal to the disease produced by these bacteria, and he has devised a method of ascertaining the resistance of an individual to a particular pathogenic organism. The results show that by proceeding by his methods the resistance of an individual may be increased to such an extent that he is enabled to throw off the disease in a way that he otherwise was unable to do.

In various septic diseases sera have been introduced which are of considerable value. Of these may be mentioned anti-streptococcus serum. At first the results of the use of this serum were disappointing and contradictory. In some cases it seemed to exercise no benefit, while occasionally surprisingly good results were obtained. Further study of the streptococci has shown that there are many varieties of these organisms, and that the serum derived from one variety may be useless against another. This led to attempts to immunise an animal against a number of different varieties of streptococci, and these attempts have in turn led to improved results.

Quite recent results have been published by Fenwick and Parkinson of the beneficial use of rectal injections of an anti-streptococcus serum in gonorrhœal infections, and certain cases of hæmorrhagic purpura. The serum used by them was one made at the Wellcome Laboratories at Herne Hill, and is there known as the "Polyvalent" Anti-streptococcus Serum, in the manufacture of which 43 different strains of streptococci taken from such different diseases as septicemia, puerperal fever, malignant sore throat, acute rheumatism, etc., are employed. (Med.-Chir. Trans. Vol. 89, p. 183, 1906.)

It is expected that this "Polyvalent" serum will remove the present uncertainty of the effects of treatment by other anti-streptococcus sera, and that it may prove an immunising agent against infection in certain operations where aseptic and antiseptic methods are not strictly applicable.

Experiments on Animals in relation to our Knowledge of Shock and how to prevent it.

Since the dread of septic troubles has been removed a very important subject to which surgeons are now directing their attention is the diminution or prevention of shock. Some of the most valuable operations are occasionally attended by the occurrence of severe and even fatal shock. As the result of much experimental work we are improving our methods in the way of preventing this calamity.

The investigations as to the relation of the vasomotor nerves, the medulla, and spinal cord to shock, and as to the influence of injections of supra-renal capsule, of adrenalin and other vascular contractors, all depend on physiological experiments.

Many of the researches on blood-pressure, on the nervous regulation of the blood-vessels, etc., which seem of more scientfic than practical importance, have a direct bearing on this question of shock, and should be encouraged, as they are tending in the direction of helping us to obviate this danger in surgery. All the vascular contractors have been discovered by experiments on animals, and there is much yet to be learnt about such drugs in inflammatory diseases and hæmorrhage (A. R. Cushny).

Other witnesses will not doubt bring testimony to bear on the importance of the experimental study of the action of drugs on the therapeutical treatment of diseases.

Mr. H. Morris. P.R.C.S.

8 May 1907.

II. and III.

Experiments on Animals in relation to the Bacterial Origin of Certain Diseases, and the Immunising and Curative Influence of Culture Sera.

In illustration of the necessity of continuing experiments on animals if the benefits which are obtainable from them by immunising, preventing, and curing certain diseases in man and animals are not to be checked or altogether to cease, I will mention the following diseases:—

A.—Diphtheria.

The Klebs-Loeffler or diphtheria bacillus was first described by Klebs in 1875, and was obtained in pure culture by Loeffler in 1884. Its isolation from other bacteria which are also found in the mouth was a matter of great difficulty and the work of many years.

Behring and Kitasato in 1890 cleared the way for immunising healthy animals against, and curing infected animals of diphtheria, but it was not until 1897-1898 that Park isolated the particular strain of bacillus and obtained the particular toxin, which was of a power of sufficiently high virulence to produce an antitoxin of regular and standardised strength.

For the continuation of the antitoxin treatment to be possible two sets of vivisectional experiments must go on:—

(1) The inoculation of guinea-pigs to standardise the strength of the toxin and the antitoxin; and

(2) The inocluation of the horse with the toxin; and

(3) The venesection of the horse to obtain the serum or antitoxin.

By No. 1 the minimal lethal dose of the toxin, or poison derived from the pure culture of the diphtheria bacillus, and the minimal quantity of serum required to neutralise the same are ascertained; 10,000 guinea-pigs a year for this purpose have been used in Ehrlich's laboratory, and about 2,000 a year were used at the laboratories on the Embankment for the same purpose.

Animal inoculations are required also for diagnostic purposes, and as a protection of the community against infection from persons convalescent from the disease. It is now the practice in the Metropolitan Asylums Board hospitals, as it has been for several years past in New York, to examine the secretion on the throats of patients who have recovered from diphtheria for the presence of baccilli. Any organisms resembling diphtheria bacillus are tested on animals not only to establish their virulence, but also to recognise that it is the diphtheria bacillus. One guinea-pig is injected simultaneously with a broth-culture of the suspected organism. Another guinea-pig receives the same kind of injection with the addition of a small quantity of diphtheria antitoxin. If the organism is virulent diphtheria bacillus the first guinea-pig will die, whereas the second will be quite unaffected.

At the Metropolitan Asylums Board laboratories the inoculation test on animals is also used for the diagnosis of cases occurring in the hospitals of tuberculosis, glanders, and cerebro-spinal meningitis. The milk supplied to the hospitals of the Board has also been tested for the presence of tubercle by the inoculation of guinea-pigs.

The diminution in the mortality from diphtheria since the introduction of the antitoxin treatment is considerable. There are numerous reports and statistics easy of access which prove the truth of this statement (Clinical Society's Transactions, and Stephen Paget's Book).

As in the case of the animals used for cancer research, so in the case of the horses used for obtaining diphtheria antitoxin, I can from personal inspection testify to the extreme care and attention and the great liberality as to fodder bestowed upon them, and to the absence of any painful or deleterious effect on them as the result of the injection and subsequent bleeding.

B.—Tetanus.

About 1884 Nicolaier showed the real microbic cause of tetanus to be a bacillus in earth and dust, which, when injected into the tissues of animals, produced tetanus in the animals so treated. Rosenbach, about the same time, found the same bacillus in a patient suffering from traumatic tetanus. The identity of the bacillus of tetanus in man with Nicolaier's bacillus of earth was demonstrated in Koch's laboratory in April, 1887. In man the bacillus has been found in the wound-secretion, in the nerves leading from the seat of infection, and in the spinal cord of patients suffering from tetanus. The bacillus has been found also in surface soil, in street dust, and in the dust of old buildings, such as churches, etc.

Though it cannot be said that any one of the tetanus antitoxins has been found to be a curative agent in the disease, the preventive use of tetanus-antitoxin for the immunization of men and animals has given great results (see for the results obtained in the veterinary practice in France, the Med. News, 7th July, 1900; and for the results obtained in a large number of horses in the United States of America, see Med. Annual, 1901).

The preventive use of antitoxin in the human subject was shown in an outbreak of tetanus at Prague in 1899. (Paget's Book.) H. J. Scherck gives a strong proof of the power of antitetanic serum as an immunizing agent in man in relation to the injuries caused by toy pistols during the 4th July or Independence Day celebrations in America. (See "The Journal of the American Medical Association," August 18th, 1906, pp. 500, 505, and 512.)

The modern study of tetanus has done away with the useless operations of nerve-stretching and nerve-dividing, which were based on the fallacious theory that tetanus is an ascending inflammation of a nerve, It has led also to the more frequent, early, and complete excision of the wounded tissues, because it is now known that the bacilli, at the outset, are limited to the tissues in the immediate area of the wound. A certain number of cases of chronic tetanus have been reported as cured by the tetanus antitoxin. Injections into the spinal sheath are reported to have cured three patients out of four; and a fifth case, namely, that of a boy into whose nerves and spinal subarachnoid space the antitoxin was injected, is stated to have been cured. Still, other successful cases have been reported recently. ("The Medical Annual," 1905, p. 80; and 1906, p. 53.)

C.—Hydrophobia.

Rabies is another disease the scientific study of which only commenced four years after the date of the 1876 Act. Though a prolonged search for the specific microbe has not hitherto been attended with complete certainty of success, yet, quite recently, Professor Negri, of Pavia, has found, in 50 out of 52 cases, a micro-organism in the nerve-tissues of animals dead from rabies ("Med. Annual," 1906, p. 418).

Renault and Lannelongue discovered some years ago that rabbits could be successfully inoculated with the saliva of rabid animals, such as the dog, fox, jackal; and later, Pasteur produced the disease in the same way. Though the specific microbe remained unidentified, it was ascertained and put beyond doubt that the essential cause of hydrophobia is a specific virus which can only be reproduced within the living body. Another convincing proof of its microbic origin was established by artificially producing the disease in healthy animals, by implanting in them fragments of brain or spinal cord tissue taken from animals dead of rabies. By transmitting the virus contained in nerve tissue through a series of rabbits, Pasteur was able to obtain a standardised virus of exact strength and having a known period of incubation (six days). He was also able to attenuate the virus in the nerve tissue by drying the spinal cord taken from animals dead of rabies—the greater number of days it was drying the weaker became the virus in the spinal cord. In this manner, he was able to have always on hand cords of different strengths of virus for use in different cases, just as a pharmaceutical chemist keeps on hand the same drug of different strengths. The essence of Pasteur's treatment is to render persons artificially immune before the disease caused by the bite has had time to act. Thus a man who has been bitten by a rabid animal can be immunized by inoculations whilst the disease is still dormant, with a succession of doses of graduated strength until he has within himself enough antitoxin to make him proof against any outbreak of the disease.

It is clear, therefore, that in order to maintain a constant supply of antitoxin, rabbits must be inocu-

lated with the virus to yield, immediately after being killed, spinal cords suitably affected by the disease.

Although up to the present prevention and not cure has been obtained by the antitoxin treatment, yet thousands of human lives have been saved by its immunizing power, and the mortality is absolutely undoubted cases has been reduced to less than 1 per cent. (Stephen Paget). I would like to add here that from a report published in "Annales de l'Institut Pasteur" (p. 411, vol. 1905) for the year 1904, it appears that of 755 persons who underwent the antirabic treatment at the institute only three died. This is a mortality of 0·39 per cent. This mortality will be still further improved if Negri's bodies are found to be the specific cause of the disease, because the suspected animal which has bitten a human being, or another animal, if at once killed and its nervous system examined, will show the presence therein of the micro-organism, and then the immunizing treatment would be commenced at once, instead of waiting to see if the offending animal develops rabies or not. Thus the proof that Negri's bodies are the real cause of rabies would be a discovery of the greatest diagnostic value, because most of the fatal cases which occur during or after the antitoxin treatment have been in persons upon whom the treatment was commenced too late to take effect. Though the detection of the organism of Negri in the nerve tissue of the animal which inflicted the bite would be a matter of microscopical or culture examination, still animal experiments will be required to test whether the organism complies with the three postulates of Koch before it can be admitted to be, or not to be, the cause of the disease. Again, if by an "intensive" modification of Pasteur's treatment a cure is ultimately to be discovered, it can only be by by further experiments on animals.

It is a satisfaction to know that rabies in rabbits is of a painless paralytic kind, and that these animals do not suffer from muscular contractions as men, dogs and other animals do.

D.—Anthrax.

Anthrax (called also charbon, splenic fever, or splenic apoplexy, malignant pustule for the sore at the site of inoculation in man, and woolsorters' disease when the lungs are infected after inhalation of the spores of the bacillus anthracis) occurs in human beings, especially in those engaged in avocations having to do with hides and the wool or hair of animals, and in rag pickers. It affects sheep, cattle, horses, pigs, and goats, and is transmissible to guinea-pigs, rabbits, mice, and sparrows. It spreads amongst animals by means of the germinating spores of the bacillus which attach themselves to plants and grass, and which, when taken in with the food, become the cause of intestinal anthrax. Pasteur showed by injecting guinea-pigs with particles of earth, how flocks were exposed to infection, merely by grazing over certain fields. Anthrax was the first of the infectious diseases definitely proved to be of bacterial origin. As long back as 1849, little fine rod-like bodies were first observed in the blood of sheep dead of anthrax; in 1863 Davaine first proved that these rod-like bodies were living organisms (which he called bacteridia) and were present in the blood of every animal affected with anthrax; and later still, Koch succeeded in making cultures of them and reproducing the disease by inoculating other animals with these cultures. But even in 1876 and later it was denied that the bacillus anthracis was the cause of anthrax, until Pasteur's work finally settled the question in 1881. Inoculations against anthrax have now been employed since 25 years ago, and wherever employed the losses from the disease have sunk into insignificance. Sheep and cattle are inoculated with the attenuated virus known as the anti-charbon vaccine. This vaccine is obtained of different strengths by cultivating the anthrax bacillus in neutralised bouillon at different temperatures and for different lengths of time. It is found that a second inoculation with a vaccine of greater strength than that used for the first inoculation in the same animal, gives a greater degree of immunity and protects the animals against the most virulent form of anthrax. The inoculations are not altogether free of danger, and a certain number of sheep and cattle—though an excessively small proportion—die as the result of the inoculation. Millions of sheep and half a million of cattle were inoculated in France in the 12 years 1882-1893. The result of the treatment of the mortality from charbon, including the mortality from the inoculations, was to reduce it from 10 per cent. to 0.94 per cent. in sheep and from 5 per cent. to 0.34 per cent. in cattle. M. Chamberland (Annales de l'Institut Pasteur, March, 1894, p. 163), from whose report these figures are taken, estimates that the money advantage of these inoculations to French agriculturists amounted at the least to 5,000,000 of francs in respect to sheep, and to 2,000,000 of francs in respect to cattle.

Mr. H. Morris, P.R.C.S.

8 May 1907.

E.—Glanders.

Glanders or farcy, which originates in the horse and occurs in man by contagion, is a disease caused by a specific microbe, namely, the bacillus mallei. This disease is very rife among horses, and is stated to be on the increase. Tigers, lions, cats, sheep, goats, asses, and other animals, are susceptible to inoculation with the virus of glanders. In man, it occurs in the acute and chronic forms, and is exceedingly fatal in the acute. When man is the subject of glanders, diagnosis is rendered positive by detection of the bacillus in the nodules, the pus from the sore, the sputum from the lungs, and in the fluid of an affected joint. Numerous bacilli are also found in the blood of man more constantly than in the blood of glanderous horses. Treatment is still most unsatisfactory.

Though glanders has been known for centuries, it was not until 1882 that the bacillus of glanders was discovered; later it was cultivated on sterilised potato and on solid, sterilised blood serum at a temperature of 104 deg. F. Inoculation experiments with the culture were made on horses, guinea-pigs, rats, and rabbits, to prove the identity of the cause of the disease. Test inoculations with mallein are largely used on horses before they are put into stables with other horses, to ascertain whether they are or are not in an incipient stage of infection. Up to the present, however, no preventive or curative antiglanderous vaccine has been discovered, though future experiments may, it is to be hoped, furnish one. The knowledge of the cause of the disease has led to greater care being used with regard to sponges, cloths, etc., used by grooms and ostlers who are themselves in consequence less likely to be infected.

F.—Graves' Disease.

Graves' disease is nowadays treated with very marked improvement in all symptoms, and in some cases with complete cure as the result, with antithyroidin—*i.e.*, serum removed from goats after removal of their thyroid gland. ("Medical Annual," p. 54, 1906.)

IV.

Experiments on Animals in Relation to Cancer Research.

In the matter of cancer, it is important to point out that before the establishment of research laboratories, and up to 1902, cancer had been studied almost exclusively from the clinical aspect, and by pathological, histological, and chemical examinations of the dead cancerous tumours. The result has been that our ignorance as to the cause and origin of cancer at the beginning of the twentieth century was almost as profound as ever before. Hence the importance of studying living cancer-tissue by transplanting it from animal to animal; and mice were selected as the subjects of the great majority of the experiments, because the disease occurs spontaneously and frequently in them.

To keep the tumour-tissue alive, and to provide a sufficient and continuous supply of it, large numbers of inoculations are essential:—

(*a*) Because many of these inoculations fail entirely;

(*b*) because in many instances the tumours which arise and for a short time grow in mice, subsequently atrophy and disappear;

(*c*) because of the small amount of tumour-tissue obtainable from each mouse;

Mr. H. Morris, F.R.C.S.

8 May 1907.

(*d*) because the step by step investigation of the changes which take place at the site of inoculation entails the sacrifice of a large number of animals at every stage; and

(*e*) lastly, because the investigation of the secretions and body fluids of cancerously affected as compared with unaffected animals requires the use of a large number of mice.

If it be asked what, up to the present time, has been learnt or confirmed by all these experiments, the answer is:—

(1) Positive knowledge has been gained that this mouse tumour, which is identical in nature with the human mammary tumour, grows by an inherent growth of its own, and is not due to a change in the tissues themselves of the animal into which it is engrafted.

(2) That cancer can, and does, not so very infrequently, disappear spontaneously.

(3) That the animals in which cancer has grown and then disappeared are immune to fresh inoculation.

(4) That a mouse can be rendered immune by the injection into its body of some of the blood of a healthy or an immunised mouse.

It should be pointed out in reference to these inoculation experiments that they are practically painless; or, if pain can be said to be caused at all, it is but slight and momentary, and to be compared in the human subject with the pain caused by a simple subcutaneous puncture.

Neither is pain suffered by the animal in which the transplanted tissue grows even into a large tumour. It is only in the exceptional cases, in which the tumour ulcerates, that any pain occurs, and as this condition renders the tumour useless for further experiment, the animal is at once killed.

Evidence as to the painlessness of these growing tumours is afforded by the activity of movement, sleekness of coat, and general healthy appearance of the mice, their indifference to pinching or pressure of the tumour, which is not innervated; and further, by the fact that when they have been kept in separate compartments of the same cage they have eaten through the partition, mingled with one another, and a litter of young ones has been the result.

Every cutting operation in these investigations is performed under complete anæsthesia, and precautions are always taken to secure a septicity and immediate healing of the wound.

As regards other animals, inoculation experiments have been undertaken to a very limited extent on horses, dogs, rats, rabbits, frogs, and fish. Only in the case of the rat and dog have inoculations been followed by the development of the disease, and to these the same remarks apply as in the case of the mouse.

Any limitation placed upon the number of inoculations, whether in mice or in other animals, including anthropoid apes, to which resort may ultimately be necessary, will have a disastrous effect on the further development and the prosecution of cancer research in this country. It is at present impossible to determine how far the contrast between the success obtained in mice and the failure in other animals, is due to the discrepancy in the number of inoculations made.

As a member of the Executive Committee of the Imperial Cancer Research from its outset, I have had frequent opportunity of witnessing the complete absence of suffering in animals the subjects of these cancerous tumours, and of observing the extreme care and attention given to all the animals, both in London and at the farm.

Experiments on Animals under Certificates B. and C.

The foregoing observations have had reference almost entirely to inoculation experiments; but I should not complete the description of the importance of vivisection to the progress of surgery were I to omit altogether the mention of experiments of a larger kind.

I must refer in this connection to the localisation of the motor centres in relation to brain abscess, brain tumours, and brain injuries, and to the operation of trephining for these conditions.

I would not for a moment wish to imply that much had not been learnt as to the localization of function from clinical observation apart from experiments on animals; but I do not think it can seriously be contested that the extent and rate of acquisition of our knowledge of this subject, the precision of our knowledge, and the confirmation of what had been otherwise learnt, have been most important results of experiments on the brains of animals.

When it was pointed out that it was, possibly, not so much the original escape of bile, after rupture of the gall-bladder, etc., which brings about the fatal result, as the continual filtration of bile into the peritoneal sac, the question arose as to how far surgery could afford aid in preventing the further escape of bile in this kind of injury. To this end M. Herlin and M. L'Anglas made experiments on dogs and proved that these animals could live after their duct had been tied or the gall-bladder removed. Laparotomy in man followed by suturing the gall-bladder, tying its duct, or removal of the gall-bladder, has since saved a good many lives.

Dr. V. Czerny, to investigate the question whether the larynx could be extirpated without death resulting, performed a series of experiments on eight dogs, all of which underwent total extirpation of the larynx. The first four died from the consequences of the operation. The last four survived and remained well. It having been thus shown that the larynx in not indispensable to life, and that the operation is feasible, extirpation of the larynx became a recognised surgical operation. To what perfection it has been brought, may be seen from the results described in the latest contribution on the subject by Dr. Chevalier Jackson, of Pittsburgh ("British Medical Journal," November 24th, 1906). Of eight consecutive cases of total laryngectomy for laryngeal cancer not one patient died from the operation; one lived 7 years, one 3 years, one apparent cure was lost from observation, three recurred within one year, and one is too recent to record. One died from alcoholism eight months after operation. It deserves particularly to be mentioned that once the feasibility of removal of the larynx having been shown, Czerny's experiments have never, so far as is known, been repeated.

The repetition of operations of an experimental kind on animals has, however, often been the prelude to the adoption of most important operations on man.

Take, for instance, nephrectomy or extirpation of a kidney: Zambeccarius in 1670 and Roonhuyzen in 1672 and several others in the beginning of the 19th century, had shown by experiments upon animals that life could be well maintained after removing one of the kidneys. Still, when Gustav Simon of Heidelberg in 1869 wanted to relieve a woman of a distressing condition, and could only do so by removing the kidney, he was reluctant to operate without first making experiments for himself. He knew that pathology afforded him many instances of persons living after one kidney had been rendered gradually useless by slow disease, but he wanted to confirm, if he even knew of them, the experiments by others which showed that the sudden withdrawal of the functions of one organ could be physiologically tolerated. He wanted also to know what were the immediate risks of the operation as distinct from the risks of interfering with the urinary functions—the risks namely of hæmorrhage, of embolism of the renal vein, of pyemia, etc. Hence his careful observation of fifteen hysterectomies on bitches contrasted with the same number of nephrectomies on dogs. (Hunterian Lectures, 1898, H. Morris.)

Again, when the numerous operations on the stomach and intestines for short circuiting, excision, etc., were rendered possible by the great safety with which the abdominal cavity could be opened and dealt with under aseptic precautions, surgeons were anxious to test for themselves the various methods and modifications of methods, for suturing the bowel, though these or some of these had been employed in experiments on animals, as well as in cases of injury in man, by surgeons of some centuries before.

It shows only a praiseworthy and natural solicitude and anxiety on the part of the surgeon that, before adopting a new operation on a human being, he should, as far as possible, test it beforehand on one of the lower animals under conditions and circumstances as nearly as possible similar to those of his patient.

7727. I understand that there are some matters which you would like to mention in addition to what you have stated in your *précis*?—In the first place I should like to add—it may have been already before the Commission, and, if so, I hope you will stop me, but it may be of some interest if it has not—the matter of antitetanic serum. Tetanus has been, as you may know, a

very common affection after wound inflicted during the celebrations of July 4th (Independence Day) in America.

7728. It was mentioned by some witness, I think, and I think you mentioned it in your own *précis*?—Yes, but I have got some figures here, if you care to hear them. For instance, the use of the prophylactic anti-toxin was introduced in 1904. In 1903 the number of these tetanic cases (this, of course, only goes to a certain extent as being valuable) was 415, and in 1906, after the use of anti-tetanic serum for all those who have been wounded or injured, the number of cases was only 89.

7729. Are you speaking there of New York?—Yes. Of course it depends, you will say, upon the number of people injured. I do not think I have quite got that out—I mean the proportion of injured to those who get tetanus; but there is the fact that the number of tetanus cases in 1903 was 415; and (after the use of the tetanus anti-toxin) in 1905 there were 105, and in 1906 there were 89.

7730. (*Dr. Wilson.*) Would they be wounds derived from fighting or from what is called gravel rash?—Mostly from pocket-pistol wounds, fire-works, and things of that sort—small wounds. They pick up in the streets bits of anything, bits of wood or paper, or anything of the sort from the dust and mess in the street, and put those into the pistols and fire these off as a sort of sport, like back-scratchers in our own streets; and those produce a certain number of wounds; and being produced though by small force, yet by an article which is impregnated with dirt and soil, they are very prone to produce tetanus. And then the introduction, for all those persons so wounded after these celebrations, of the anti-tetanic serum has had that effect in reducing the number of cases which occur.

7731. But would not a great deal depend upon the condition of the streets and the kind of weather—whether it was a fine day or a dirty day?—That does not touch the point, so far as I see. The question is, the liability of wounds to tetanus derived from a particular source, and here is the same cause one year as with the other, producing wounds of the same kind; and by the use of the anti-tetanus serum the proportion of cases of wounded persons who get tetanus as the result of those wounds is much diminished.

7732. (*Chairman.*) I think what Dr. Wilson meant was when there were 89 it may possibly have been a wet day, when all the dust and dirt was kept down, and it did not therefore cause the same number of cases; there may have been over 100 people wounded, and 90 per cent. of the 100 may have died; whereas in the other case it may have been a very dusty day, when the tetanus bacillus was very much about, and the 400 may have shown a less mortality per cent. than the 90. It is subject to that observation?—Of course, the 4th of July comes in the same time of the year, and generally under the same kind of conditions as to weather in America.

7733-4. (*Mr. Tomkinson.*) Were all these cases treated in the public hospitals? Do you know they are all treated with this serum?—I do not know that they are all treated. I know that they endeavour to treat all that are thus wounded. It is some time since I looked at any of these papers, because at the last moment I was rather suddenly summoned before this Commission; but I find, looking down a little lower in my notes, that I have the numbers wounded. The tetanus cases have diminished on the 4th July, but the number of wounded have risen from 4,449 cases in 1903 to 5,466 in 1906.

7735. (*Chairman.*) That quite answers Dr. Wilson?—And then, with 4,449 wounded in 1903, we have 415 cases of tetanus, and with the 5,466 in 1906 we have 89 cases of tetanus. The reference to these figures is "The Journal of the American Medical Association," August 18th, 1906, pp. 505-8.

7736. (*Colonel Lockwood.*) Is that in the United Kingdom?—No; in America.

7737. That is why you mentioned the 4th July?—Yes.

7738. (*Dr. Wilson.*) But do not you think it is possible that they had such a fright in the first instance that they would feel more careful about cleaning any wounds?—These statistics have only reference to a year or two, and it is difficult to arrive at any absolute conclusion from them perhaps. I do not want to press the point further.

7739. (*Chairman.*) I quite see the point. You admit that you cannot take it from the figures precisely—that the argument does not go up to the figures, as it were; but that a general presumption arises from the figures?—Yes. Without taking it as absolutely accurate it is a very striking effect.

Mr. H. Morris, P.R.C.S.

8 May 1907.

7740. And allowing for other possible causes?—I refer on this same subject to a paper by Scherck. He gives a record of 291 injuries caused by these toy pistols in America during the 4th of July celebrations. The injured persons were immunized by the antitetanic serum without a single case of tetanus occurring, and Dr. Scherck compares these results with those obtained in a year when no serum was used, and in which nearly one-third of the injured succumbed to tetanus. That is merely in support of that statement. Then there is another point I thought it would be of some value to refer to, and that is, in the matter of the treatment of anthrax, or wool sorters' disease, or whatever name you know it by, by means of the anti-anthracic serum ——

7741. Are you speaking of anthrax in mankind?—Yes. I have here from Dr. Legge, of the Factory Department, a letter, and also a copy of the Annual Report of the Chief Inspector of Factories and Workshops. Perhaps that is in the possession of the Commission. I only want to draw attention to what he says there. He says: "There is, I think, a consensus of medical opinion that in cases of cutaneous anthrax it" (that is this serum) "is a very valuable remedy. In internal anthrax administered subcutaneously it did not prevent a fatal issue in any case last year." A little lower down he says that in one case in which the serum was used the person recovered, and he gives here a table where there are cases of recovery after the use of the serum; and he gives me in a private letter which I have here some further information, which, perhaps, it will really be shortest if you will permit me to read.

7742. If you are only going to state what Dr. Legge says, I may tell you that he is coming himself as a witness?—Very well; but I can say it is distinctly favourable, and that at St. Bartholomew's Hospital now the only treatment in the last few cases of anthrax that they have had there has been the introduction of this serum of Sclavo.

7743. (*Colonel Lockwood.*) Are they all successes?—They are all successes; and Dr. Legge will give you a table of cases which are more recent than those which he gave in his Milroy lectures before the College of Physicians in 1904 or 1905.

7744. (*Sir Mackenzie Chalmers.*) He has been working at it during the last three or four months?—Yes. Then another thing, perhaps, also has been before the Commission, and I pray you stop me if it has—that is with regard to the work in the Japanese Army.

7745. (*Chairman.*) I do not think we have had anything more than a casual reference to it?—Baron Takaki has said: "As one example of the results and terminations of treatment I give you a short account of the hospital established at Hiroshima. The hospital was established in April, 1904, and the report covers the time up to November, 1905. During this interval the hospital admitted 203,782 cases, whence 162,885 were transferred to other hospitals; but the average number of patients in the hospital was about 5,000, and the largest number the hospital had at a time was 10,000. Almost all serious cases were kept in the hospital, because they were unfit for transportation. Yet the result was so good that the ratio of death and invalided is a little above one per cent. Almost all the wounds of the soft tissues healed within ten days. Those with injuries to the bone have obtained favourable results, excepting those who were wounded at the siege of Port Arthur. The many men who were wounded in the head and chest have recovered from the wounds received; and there were also many cases of aneurysmal varix, wounds of nerves requiring operations. The number of operations performed at the hospitals amounted to more than 3,500." That is from Takaki's "Military Hygiene of the Japanese Army."

7746. I suppose something would depend upon the race there. You might have a race which had very few unhealthy members in it?—There, again, my Lord, other factors come in, of course, but still, from what we know of armies of all times and in all countries, it is a very remarkable result. These results ought to be contrasted with what obtained in the Franco-Prussian War. Neléton, the famous French surgeon, in despair at the high death-rate attending almost all operations

Mr. H. Morris, P.R.C.S.

8 May 1907

on the wounded, declared that he who would conquer purulent infections would deserve a golden statue. That golden statue is really almost deserved when you find under the circumstances of war that only one per cent. out of such a very large number of wounded and operated upon were fatal.

7747. He does not give the percentage in the Franco-Prussian War?—No, not here. Those figures are to be easily obtained, however, of course.

7748. (*Dr. Wilson.*) Have you any statistics with regard to the South African War?—No, but they are published, I believe.

7749. They are not so satisfactory as the Japanese?—I have not got them here.

7750. (*Chairman.*) That is the percentage of those who died of wounds—not of disease?—These are wounded, yes. Then I would like also to mention a statement which I have had from Sir Samuel Wilks, who was the pathologist at Guy's many years ago. He writes, and says: "The discovery of impurities getting into the system being the great cause of the mortality after injuries and operations, led to the improved modes of dressing introduced by Lister. So that the greatest operations may now be performed with safety. All this is well known to the surgeon, but it came home to myself in an almost startling manner from what I witnessed in the post-mortem room. Some time before, when writing a paper on pyemia, I had no difficulty in collecting a hundred cases which had occurred in a very short period previously, when suddenly this terrible malady disappeared, it was gone, never to return." He says he had the greatest difficulty in finding in more recent researches any records of pyemia that have occurred recently.

7751. Of course, the importance of all this to us is only with reference to how far this is owing to experiments on animals. You have already given us your view about that?—Yes, and these are further illustrations—that is all. There is one other matter that I think I have not mentioned in my paper, which I should like to say one word upon, and that is, the desirability of retaining the power on the part of lecturers on physiology of giving demonstrations to classes. I think it is a matter of importance that they should still have that power. These exhibitions are of very great importance in teaching classes.

7752. Is the importance that you attach to that with reference to enabling students to follow what the structure or the nature of the disease is from inspecting the animal, or to teach them how to operate?—I am not suggesting that there should be experiments on animals for the purpose of teaching how to operate; but I am suggesting that it is very important to retain the power that still exists on the part of physiologists to give a certain small number (and they always are but few) of demonstrations to classes who are learning the functions of the body; for instance, to know what the action of the heart is like and what the action of the intestines is like, and the effect of influencing the organs through irritation or section of different nerves. There are a few things of that sort which can only really be fully and completely impressed upon the student by having practical demonstrations of them; and they are performed in small classes (not in a great theatre), before a group of students, upon animals, which are under an anæsthetic and are killed as soon as the experiment is over, and before they are allowed to come round from the anæsthetic. This is merely one of the things that concerns the teaching of the sciences of the profession to which many of us attach a good deal of importance.

7753. Did those demonstrations and experiments take place in your student days?—Yes, I believe Guy's was one of the few places in London where they were shown, but I was a pupil of Dr. Pavy at Guy's Hospital, and Dr. Pavy used to show us a few of these things. There were not many experiments, perhaps only four or five in the course of a whole session; but I can say from personal experience how one was impressed by the sight for a few minutes of a thing of that sort, which no amount of reading or verbal descriptions or lectures would ever have given to one.

7754. Was that before or after 1876?—It is so many years ago that it goes back to before 1876.

7755. Before the Act of 1876?—It goes back to before the Act of 1876, because it must have been in 1867 or thereabouts. I do not remember quite the exact date. Among the questions that were put to some of the witnesses in 1876—I think to Sir James Paget and Dr. Pavy himself—one had reference to a certain regulation which is printed in the College of Surgeons' Calendar in the regulations relating to the education and examination of candidates for the Fellowship. It is there stated that a course of practical physiology must be attended at a recognised school, and questions were asked as to what practical physiology meant. We have, in our Calendar since 1874, had the following note: "By this is is meant that the learners themselves shall individually be engaged on the necessary experiments, manipulations, et cetera, but it is not hereby intended that the learners shall perform the vivisections"; and in case these regulations before you now I should like to explain that although we expect them to have seen the experiments, we do not expect them to perform them themselves.

7756. That I quite understand?—Perhaps 20 men will see an experiment which is shown by a lecturer.

7757. (*Sir Mackenzie Chalmers.*) Who is a licensed person?—Who is a licensed person, and who is, of course, an expert in the manipulations required for; but they are not to be performed by the students individually.

7758. (*Colonel Lockwood.*) Not necessarily?—No.

7759. They could not do so without a licence?—No.

7760. (*Dr. Gaskell.*) Is that regulation still necessary for the Fellowship?—Yes; it still appears in this set of regulations, but it has that note in italics.

7761. There is no such regulation for membership?—No.

7762. It is for the Fellowship?—Yes.

7763. (*Sir Mackenzie Chalmers.*) What is the actual number of Fellows of the Royal College?—There are either 1,300 or 1,350—I think 1,350. But the number of men who come up at each batch—and the examinations is held twice a year—perhaps varies from 50 to 70.

7764. (*Dr. Wilson.*) Would it necessitate a certificate from the teacher that the candidate for the Fellowship has attended such demonstrations?—Yes.

7765. (*Chairman.*) Is that all you wish to add?—If you please.

7766. (*Colonel Lockwood.*) How is it known that experiments on living animals are going to take place at these lectures? Are they called "A Course of Physiological Lectures," and it is understood that they will include experiments?—As I have said, only on very very few occasions are there any experiments on animals, perhaps only on four or five, or, at the utmost, half a dozen, in the course of a winter session.

7767. How will the men know?—Those men who are attending the lectures would be informed at the end of a class—this is the way I have known it done—that at the next lecture, or the next time of meeting, there would be this or the other shown upon a living animal.

7768. Now, supposing I myself, or we will say Sir William Collins, or any member of this Royal Commission, wished to see an operation on a live animal—you will understand my motive for asking the question—and that we did not wish the demonstrator to know that we were coming, how could it be worked? You see my point. My point is that if the man was ready for me other people might say, "He knew that you were coming"?—You mean a surprise visit.

7769. Yes?—Of course, the inspector can go in at any time, there is nothing to keep him out; and the object of keeping anybody else out would merely be in conformity with that section in the Act which provides that these things are not to be for public exhibition. But if you were to go to and say, "I am very much interested in seeing this experiment," there is not a lecturer in London or in the country who would not allow you to come in and witness it, I feel sure.

7770. But you see my point. Other people might say, "It is quite true that you went, and you saw the experiment; but the man, of course, knew you were coming, and so he conducted it more humanely than if you had not been present"?—I do not think anything of the kind. The Commission must take my opinion for what they think it is worth; but I feel satisfied that there is not a single lecturer in the country who would vary his experiment because there happened to be a member of the Commission or a member of the Anti-vivisection Society or of one of the Anti-Vivisection Societies present.

7771. I am quite content to take it so.

7772. (*Chairman.*) It is really a question of the amount of anæsthesia what Colonel Lockwood is aiming at, whether the anæsthetics are always applied fully so as to ensure the absence of pain?—I believe, most certainly, that they are. I should think the truth is that there is probably a waste of anæsthetic—that there is more anæsthetic given rather than that there is too little. In the experiments that I have seen, sometimes when it has been known that I was going to be a spectator, and sometimes when it was not, it has seemed to me that there has been rather an over-administration of anæsthetic instead of an under-administration.

7773. (*Sir Mackenzie Chalmers.*) More than you would give to a human being?—Yes.

7774. And which would entail danger in the human being?—Yes. You see, if a dog dies, it does not matter, because it is going to die at the end of the experiment.

7775. (*Colonel Lockwood.*) You gave some evidence about the Japanese. Do the Japanese make experiments on animals?—I cannot answer that; I should think they do.

7776. But you do not know of the existence of any experiments on animals?—I do not.

7777. But you would, I suppose, allow that a nation like the Japanese, who are more, I was going to say vegetarian than carnivorous, are more likely to recover from wounds, as the Indians do, than a carnivorous European?—Yes, I should think there is much in that.

7778. If we grant that Lister's and Pasteur's discoveries are facts, do you see any necessity for continuing experiments bearing on those discoveries of Lister and Pasteur?—I think there is every reason, every necessity, if we are to go on progressing in medicine and surgery, that these experiments must be continued.

7779. On the lines of Lister and Pasteur?—Yes, certainly.

7780. To perfect and continue?—Yes, and to deal with and to combat other diseases.

7781. Do you claim that these injections are a cure for tetanus, and cholera, and anthrax?—Yes.

7782. You would go so far as that?—Yes.

7783. You made your name, I think, which is a very great one, by experiments on the kidney, was it not?—I never made an experiment in my life.

7784. I do not mean on an animal. I mean operations—I apologise?—Oh, no need for that. I thought perhaps you meant experiments on animals.

7785. No, I meant operations?—Yes.

7786. Were those operations which you have conducted so skilfully, and fortunately discovered, and were you made to do them, by experiments on living animals?—Personally, not at all. The operation that I did in the first place, and was the first to do, was done quite irrespective of any experiment upon animals; that is the cutting of a stone out of a kidney. But that was not the case with regard to cutting a kidney out of the body, because Simon of Heidelberg, who was the first to do that, made a deliberate set of experiments for the express purpose of knowing various things before he submitted a patient to the operation. He, of course, knew what the effect of the loss of a kidney by disease (a slow process) was; but he wanted to know what the loss of a kidney, by being taken suddenly away, would be, and until he knew that he did not feel at liberty to perform the operation of cutting the kidney out. But the kidney which he proposed to remove was healthy—I am speaking now historically of the first operation—and the operation was deliberately planned for the removal of a healthy kidney from the human body.

7787. Total excision?—Total excision; it was a healthy kidney, and the tube running from the kidney to the bladder, which had been cut in the course of previous operation accidentally, had its end sticking out of the flesh. The consequence was that the poor woman was constantly suffering from the annoyance of urine trickling down her side or down her front, and she implored for relief from this by having her kidney removed. That led Simon of Heidelberg to make his experiments to find out what the amount of shock would be, and what would be the risk of producing that form of blood poisoning which is known as uræmia, and what would be the effect upon the health by the sudden taking away of a kidney that was otherwise healthy, except for this leakage from this tube. Accordingly, he made these experiments.

7788. He made those experiments first on an animal?—He made those experiments first on dogs and other animals, and then he applied the results to this living female patient.

7789. As regards your particular operation, you did not do that from knowledge acquired by experiments on a living subject?—Not at all from experiments on animals; but from what I had learnt by experience from operations on the liver and other organs in the human subject.

7790. Have you witnessed any or many experiments under licence?—No, not many. I have seen a fair number. In quite recent years I have seen some, since last year, for instance.

7791. Have you ever witnessed any cruelty on the part of a demonstrator?—No, absolutely none.

7792. Or any levity on the part of those who witnessed them?—No.

7793. And always under an anæsthetic?—No, not always under an anæsthetic; it depends upon the class of experiment. When I have seen an experiment to show any effect of blood pressure, or things of that sort, the animal has been completely anæsthetised; but when I have seen experiments on guinea-pigs and rabbits, or what not, for the purpose, for example, of seeing the effect of the injection of serum (some I saw the other day) those were not done under chloroform.

7794. Have you see any of those experiments on the eye?—I have not seen any experiments on the eye.

7795. But where severe pain would have been inflicted, anæsthetics, according to the licence, have always been administered?—Yes, absolutely.

7796. And the animal destroyed before recovery?—Yes.

7797. Do you look upon morphia as an anæsthetic sufficient to prevent, more than dull, pain in a living subject, used for the purpose of an anæsthetic?—No.

7798. Would you say that you could not give an animal enough morphia to make it totally insensible to pain, if that was the only anæsthetic used?—I do not think it ever is the only anæsthetic used. I bear in mind, of course, that at one time it was the great means of rendering the human subject anæsthetised before the introduction of chloroform and ether; but I think that now morphia is given perhaps as an adjunct to the administration of an anæsthetic. I would rather not express any very definite opinion about it, because, as I say, it does not come into my way; but just as I know in the case of the human subject, so I think in regard to animals; if an experiment were wanted to be done on an animal where a very small quantity of anæsthetic was given, where as little anæsthetic as could be should be given, then, I think, morphia would be a very valuable adjunct administered before the administration of the chloroform. But the complete anæsthesia would be the same with a less quantity of chloroform, if the morphia had been previously given.

7799. But you would not look upon it as a complete anæsthetic, even given in great quantity?—No.

7800. Do you think that there is enough resemblance between animals and human beings to make experiments on living animals useful?—Yes.

7801. I may take that generally from what you have told us?—Yes.

7802. How long can an animal be kept under anæsthetics, would you say?—I have seen an animal kept under chloroform, I suppose, for two hours.

7803. At a stretch?—Yes, at a stretch, but then I have seen a living human subject often kept for as long a time.

7804. (*Sir Mackenzie Chalmers.*) What is the longest time with a human subject that you have seen yourself?—I could not answer that question off-hand, but I should think the longest time I have ever seen a

Mr. H. Morris, P.R.C.S.

8 May 1907.

human subject under anæsthetics was between three and four hours for the treatment of complete compression for an abdominal (aortic) aneurism.*

7805. (*Colonel Lockwood.*) Up to the present time do you think there has been any hindrance to science and to your profession generally by the regulations issued by the Home Office for experiments on living animals?—No, I cannot say that I do think so. I think the present Act of 1876, under which vivisectional experiments are done, was amply protective against cruelty to animals and sufficiently free and liberal for the due prosecution of proper scientific and physiological inquiry.

7806. Would you object to any further regulations?—Yes. There is one respect in which I should like to see greater freedom. Under the Act, of course, the Home Secretary can grant a licence to anyone. I should certainly like to see the thoroughly trained first aids in the laboratory permitted to do such very slight and mechanical operations as the injection of a small quantity of serum. There are a very large number of animals treated by this serum injection, and if you are injecting a considerable number of them it requires, as things are now, a highly-skilled man to spend a great deal of time in the work of just injecting the serum which these men who are trained assistants in the laboratories could do quite as easily and quite as completely and safely as the director himself does. It is a great waste of time, and is a great hardship upon the director to have to do all that simple routine work.

7807. (*Sir Mackenzie Chalmers.*) What you mean is that you think the licence should cover Certificate A, so to speak, for the assistants?—Yes.

7808. It is only Certificate A you are referring to?—Yes.

7809. You think that when a man of established character holds a licence and Certificate A, the Certificate A should extend to any able assistant of his?—Yes, either on the recommendation of the director, or it may be by having a certificate filled up as now for the director himself; but I certainly think that power should be given to a man who has been for a long time, and is, highly trained in this kind of simple laboratory work, to do it, merely to save labour to the scientific man himself.

7810. (*Colonel Lockwood.*) I suppose I may take it that you naturally would object to the exclusion of dogs from experiments?—I should certainly.

7811. You think it would be a hindrance to science?—Yes, a very material hindrance.

7812. You have read, very likely, the evidence of previous witnesses before this Commission?—I have.

7813. Are there any remarks you would like to make as regards the evidence of the witnesses who are opposed to vivisection?—If I had the material before me I could write pages of objection.

7814. But nothing strikes you particularly as very false or very wrong?—That is rather too wide a question, I think, to put to me, because I have not it all quite at my finger-ends.

7815. Of course, you know the very strong feelings that exists in the minds of many people as to the propriety of any experiments on living animals?—Yes.

7816. What do you think is the foundation of that feeling? Do you think it is simple romance, or that cruelties have existed and do exist abroad, undoubtedly; or what do you think is the foundation for this very strong prevailing feeling?—There are many words one could apply.

7817. Ignorance, I suppose is one?—I should rather not use any words to give offence, but I think it is not unlikely that a good deal of the feeling against all forms of experiments on animals, is due largely to what you have alluded to, the, shall I say, recklessness and the indifference perhaps on the part of some, with which experiments have been reported as having been done, and I believe have been done, in some of the places abroad. I think that that having been spread abroad, and not having lost in disrepute by travelling, is very largely the cause which has led people who have not looked at the thing and have not considered the thing all round, and who do not really know the way in which things are conducted in this country, to take the objection that they have taken.

7818. You do not believe as a man of science, and I have no doubt as humane a man as myself, that there is any real foundation for this strong feeling that exists?—I do not believe there is an iota of foundation.

7819. (*Sir William Church.*) You told the Commission, in answer to a question by Colonel Lockwood, that you do not consider morphia an anæsthetic?—Yes.

7820. But do you think that an animal, a dog or a cat, which receives a poisonous dose of morphia or opium is in a condition to feel pain up to the time that death occurs?—No, I do not think so. They suffer no pain.

7821. But so far as sensation goes, there is perhaps no anæsthetic that we know so much about as morphia or opium, because we know that when a man recovers from a nearly poisonous dose, and recovers with difficulty, he has been quite insensible to all that has happened to him during the time that he has been under the action of the drug?—Yes, we know that equally as we do with regard to chloroform and ether.

7822. Therefore, when you told the Commission that morphia was not an anæsthetic, you meant that if used as a perfect anæsthetic, the animal would not survive?—Yes. I was assuming that Colonel Lockwood meant to ask me whether I thought that in the case of an operation done upon an animal to which morphia had been administered, the intention being, of course, that it should have an affect for the time and the animal should live afterwards, it was as sufficient as chloroform, and I said that I did not think it was. But if you are going to give a poisonous dose to an animal, then of course the operation might be done and the animal would not feel pain.

7823. I wished to put the question because we have been told here by several witnesses that opium is not an anæsthetic, and therefore even when a poisonous dose is given, the animal is probably suffering tortures until death occurs?—That is not so.

7824. (*Sir William Collins.*) I think you said that you had never yourself held a vivisection licence?—No, I have never performed any experiment.

7825. Nor have you practised any vivisection?—No.

7826. Nor have you used vivisection, of course, for demonstration purposes?—No.

7827. Nor for obtaining manual skill?—Certainly not.

7828. I gathered from one answer which you made to the noble Chairman that you rather objected to the use of vivisection for the purpose of obtaining manual skill?—Those are my feelings. I do not think it is necessary.

7829. Should I be right in thinking that many practising surgeons practise vivisection?—I should think not for that purpose.

7830. Or for any purpose?—Well, there are surgeons who practise vivisection no doubt occasionally for the purpose of ascertaining the effect or the technique of a new operation, but not as a means of demonstration, if that is what you are asking me.

7831. Shall I be right in thinking that there are many practising surgeons who have never practised vivisection?—Surely yes.

7832. I only wanted to get it from you as President of the Royal College of Surgeons, whether that was the case or not?—That is so.

7833. I understand that the Council of our College which you represent is not anxious to see, with the single exception that you mentioned of the permission to assistants in laboratories to perform minor injection operations, any modification in the existing law or practice?—I think they are content with it as it is.

7834. Shall I be right in thinking that they would regret a modification of the existing law?—I am sure that you would, if by modification you mean curtailment.

7835. Of such protection as is accorded to animals by the existing law?—I thought you meant curtailment in the way of privilege to perform experiments. I think they would regret that, but I think that they would equally regret to see any curtailment of the proper and due protection of animals.

7836. They recognise, in fact, that vivisection should be practicable, but that it should be practised under restrictions?—Yes.

* *The exact time was 4½ hours. For particulars see 56th Vol. of the Medico-Chirurgical Transactions, p. 390 1873—H. M.*

7837. I gather from your *précis* that you are anxious to state that in your opinion the use of experiments on animals has been a part cause, not by any means the whole cause, of the great improvement to which you have borne witness in the course of your examination?—That is so.

7838. And that you find a difficulty in disentangling the causes that have been at work in affecting that progress?—Yes.

7839. I think you state that it is practically impossible to allocate with precision that which has been due to vivisection and that which has been due to other causes?—Yes, I think so.

7840. That is to say, that you would not wish to underrate the importance of clinical observation, pathological anatomy, and so forth, which have also contributed to that end?—Certainly not.

7841. In the return which you put in which has been prepared by Mr. Watson Cheyne, you place Pasteur's work on spontaneous generation as the fundamental basis upon which the modern aseptic and antiseptic treatment of wounds has been erected?—I do, together, of course, with Lister's work.

7842. As one of the fundamental supports of that superstructure?—Yes.

7843. Should I be right in thinking that Professor Bastian has recently again contested the alleged conclusions of Pasteur as to spontaneous generation?—It is quite certain that he has done so.

7844. That is to say, that it is still an arguable question, so far as recent literature is concerned?—Yes, in his own opinion.

7845. And as regards Lister's work I suppose one would be right in thinking that there have been considerable modifications in the Listerian doctrine between 1876, when as Mr. Lister he gave evidence before the Royal Commission, and the present time?—I do not quite follow that.

7846. For instance, in regard to the use of the spray and drainage, and so forth, there has been a very considerable alteration in technique, if not in the principles upon which Listerism was based?—The technique of the employment of facts which he has laid down, the technique of the employment of the treatment which is based upon the facts which he has discovered.

7847. Should I be wrong in thinking that Lister laid great stress upon the use of the carbolic spray and drainage?—Quite so. Those are all modified now. The spray we know is an abolished thing.

7848. I notice that in this same Table which you have handed in, which has been prepared by Mr. Watson Cheyne three matters are marked with a ×, which implies "impossible without experiments on animals." They are "immunity," "serum therapy and immunity," and "increasing the resisting power of the body"?—Yes.

7849. From your own personal experience would you say that surgery has derived great advantage from those three matters?—I should, certainly.

7850. What would you instance as the most striking example?—On which point?

7851. On any one of the three. Take opsonins, for instance?—I should say that the case I have mentioned with regard to the use of the anti-tetanic serum is an instance of immunity, and as giving increased resistance to the body; and so with regard to anti-anthracic serum.

7852. I was asking from your own experience?—Yes.

7853. That was in America, as I understand?—Yes, but one knows of it in cases in this country with regard to the treatment of tetanus.

7854. Have you yourself used it in many cases of tetanus?—No, not in many cases, because I am happy to say that I have had very few cases of tetanus to deal with.

7855. But you have used it?—Yes.

7856. Could you say in how many cases?—I think only in three cases. I have had very few cases of tetanus; they are not common cases in this country.

7857. Do you use it with a view to prevention or cure?—Cure.

7858. Was it successful in those three cases?—I am sorry to say it was not; that is a long time ago.

7859. Not in any of them?—No, they were all advanced cases; they were cases too late for the successful employment of treatment.

7860. Should I be right in thinking that it is generally stated now that the treatment is likely to be valuable rather as a preventive than as a curative?—Yes, although there have been cures up to quit recently claimed for the employment of the serum.

7861. In the figures which you gave us with regard to the 4th July in America, I do not think you stated whence those figures were obtained—on what authority?—I referred to one paper which is here on the memorandum that I mentioned. I am not quite sure about the other figures. I could tell you if you wished to know, but I think they came from an Annual Report of Surgery.*

7862. Are they official figures?—I do not know about their being official figures, if you mean by that that they came from some Government office.

7863. Do they cover the whole of the United States?—I cannot answer that question either without further reference, because what I have is just an extract merely as to the figures.

7864. Perhaps you will be so good as to add that to your evidence?—Yes, I will.† But I have given the reference to Scherck's Returns.

7865. With regard to what is essential for the diagnosing of tetanus, is it a bacteriological test?—I fear that it is not when the disease is developed.

7866. I mean for the 415 cases of which you spoke in 1903; how would those cases be diagnosed?—I suppose on the clinical symptoms.

7867. Does the Report state that?—That I cannot say; you must allow me not to answer that question, because I could not answer it for certain.

7868. Then you refer to the case of anthrax and some cases at St. Bartholomew's Hospital. Did I rightly understand you to say that in any case in which Sclavo's serum had been used in anthrax a fatal result had occurred at St. Bartholomew's?—No. With regard to St. Bartholomew's, it has been used in the last three cases, and I have got a letter here from Mr. Bowlby referring to one or two cases. But I have not taken up the position of stating that in every case in which serum has been used the patient has recovered from the anthrax.

7869. I thought I gathered that in reference to the St. Bartholomew's cases?—In the last three cases of anthrax at St. Bartholomew's Hospital I said that they had relied upon the serum treatment only with speedy recovery of all three patients. In several cases, of course, both in Italy, this country, and elsewhere, and especially in the earlier times of the employment of Sclavo's serum, not having confidence enough in the serum, surgeons excised the pustule as well as giving serum, but as they gained confidence with the serum they have done away with the operative part of the treatment and have been relying upon the injection of the serum alone.

7870. There again can you speak from your own personal knowledge of the use of Sclavo's serum?—No. I have seen anthrax in Guy's many years ago when I was house surgeon there; but the disease does not come my way now. It is not met with in my hospital.

7871. You referred to the experience of the Factory Department of the Home Office; I do not know whether you have noticed in a recent Report that they point out that cases of anthrax appear to occur without the bacillus being found, and they insist on the importance of having regard to clinical as well as bacteriological evidence of the presence of anthrax?—Yes.

7872. Is it the case that the bacillus anthracis is not always discoverable?—It is not always discovered, but I should certainly say, with the knowledge that I have, that it is nevertheless present.

7873. In the case of anthrax do you think it is safe to argue from the experience in animals, from one set of animals to another and from animals to man?—I think so.

---

* *The reference is "The Journal of the American Medical Association," Aug. 18th, 1906, pp. 505–8.—H. M.*

† *The tetanus cases occurred in 25 different States of America.—H. M.*

Mr. H. Morris, P.R.C.S.

8 May 1907.

7874. Has it been noticed that certain breeds of sheep are quite unamenable to inoculation with anthrax, such as Algerian sheep, whereas other ordinary sheep suffer severely on inoculation?—I cannot speak as to that. The variety of cases in which sheep are affected in large numbers very largely depends on the particular locality and the fact that anthrax has been buried perhaps a long time ago, but as to different breeds I have no knowledge.

7875. You mentioned the case of septicemia in mice?—Yes.

7876. Is that poison the same when it is inoculated in field mice and house mice?—I believe not.

7877. It is quite different, is it not?—Yes.

7878. (*Chairman.*) Do you mean that it requires more, or that it gives the disease in one case and not in the other?—It is a different organism that produces the disease in the different animals.

7879. (*Sir William Collins.*) That is to say that one species of the same animal will not suffer whereas the other will after inoculation with the same poison?—Yes.

7880. You spoke of three points which Pasteur's experiments had established—first the specificity of the microbe, then its variation of virulence under cultivation, and so forth. It is not a fact that experience has shown that organisms originally asserted to be specific have been found by cultivation on various soils to undergo considerable morphological variation?—I think so.

7881. Is it true that many organisms declared to be the causes of certain diseases have subsequently been found to be not so?—I do not follow you.

7882. Take the case of sheep-pox, of which the alleged organism was at one time published with a considerable degree of confidence; was not that subsequently withdrawn?—Yes, and I believe different authorities have taken different views with regard to whether the same thing has been the cause of the disease or not. I believe that is the case now between a member of this Commission, if I may refer to him, and Dr. J. Hamilton.

7883. In reference to what disease?—In reference to the diseases in sheep, especially with regard to braxy and louping-ill, and so on.

7884. And I suppose Koch, by experiments on animals, was led to conclude that the tuberculosis of animals could not be communicated to man?—That was the report that he made here.

7885. As the result of his experiment upon animals?—Yes, but then, of course, there is the opposite view held from further investigations by the most recent Royal Commission in this country.

7886. You rather demurred to my suggestion that sapremia was to be regarded as a form of blood poisoning independent of a micro-organism?—Yes.

7887. Will you tell me what the micro-organism of sapremia is?—I do not think I can at this moment fix on any special micro-organisms.*

7888. In reply to the noble Chairman you stated, I think, that there were bacilli which worked by themselves without emitting any toxin as well as those which operated by way of toxin?—I meant to say there were bacilli whose toxin was the source of the poison and that there were others which by themselves were the source of the poison.

7889. Would you give an example of the latter class?—Tetanus is unquestionably an illustration of the toxin influence.

7890. It was the other class that I wanted?—I imagine that tubercle is largely due to the organism itself as the cause of the disease.

7891. I suppose that you would at any rate contend that there have been great advances in surgical practice which have been made irrespective of experiments on animals?—Yes.

7892. That follows from what you have already stated. The use of anæsthetics would be one of them, would it not?—Yes.

7893. Then the ligature—would that be one of them or not?—Yes, I think the ligature certainly would be. The ligature is a very old means of controlling hæmorrhage long before they thought of antiseptics.

7894. It was used by Ambrose Paré?—Yes, but it goes back to very early history; it was employed, if I remember rightly, by Celsus.

7895. You have drawn a distinction between, or, at any rate, you have mentioned aseptic and antiseptic surgery?—Yes.

7896. Was the late Mr. Lawson Tait one of the champions of the aseptic treatment?—Yes.

7897. Do you remember his views in regard to vivisection?—Oh, yes, I know that he was opposed to it, but then I must say that that would not influence me much.

7898. I was only anxious to know whether you would wish us to take it that what you stated in evidence was a uniformity of view of eminent surgeons or whether there were those who were really eminent surgeons who have taken a different view?—Yes, that cannot be denied, but they are very few in number as far as I know.

7899. Should I be right in thinking that aseptic surgery has taken the place of antiseptic surgery?—I hope so.

7900. You referred to the evidence of Sir James Paget in 1876; did you notice that in reply to one question, No. 382, he states, "I can quite believe that the ardent physiologists put more trust in the experiments on living animals than I should; and certainly those studying therapeutics and diseases think more of them than I should. I think more of the advantage of clinical inquiry. But I am very anxious that there should not be a general condemnation of experiments on animals since it seems to me that there are a number of things actually essential for the life of man, that cannot be ascertainel by other means." Could you associate yourself with that opinion?—To an extent. Certainly I think we all ought to attach the utmost importance to clinical inquiry; but I imagine that if Sir James Paget were giving evidence here to-day, instead of in 1876, he would attach even more importance than he does there to experiments on animals, from the discoveries which have been made since, and from the prospect of further discoveries that will be made.

7901. At any rate, your view would not be that, I suppose, of the late Sir Charles Bell, when he said: "Experiments have never been the means of discovery, and a survey of what has been attempted of late years in physiology will prove that the opening of living animals has done more to perpetuate error than to confirm the just views taken from the study of anatomy and natural motions"?—Although Sir Charles Bell stated that as his opinion at that time, it was not his opinion at other times, and I do not think it was the best representation of what his view really was. Sir Charles Bell made many experiments, and we know what we owe to them, but Sir Charles Bell was a man who felt very deeply the pain that these experiments caused to animals, and I have had from Sir Charles Bell's widow, and from his brother-in-law, the late Mr. Alexander Shaw, a statement that he felt it so strongly that he gave up performing experiments on animals because he hated the sight of the suffering, which they necessarily entailed. But, still, it was a good thing he performed them, because, as you know as well as I do, they were the starting point of our knowledge of the different functions of the nerves.

7902. As bearing upon what you have said, I see that Sir Charles Bell in a letter wrote as follows: "You may think me silly, but I cannot perfectly convince myself that I am authorised in nature or religion to do these cruelties." In other words, it is a conflict between the moral sentiment and scientific experiment?—And the desire to obtain knowledge from scientific investigations for the benefit of humanity. I think all those things entered into Sir Charles Bell's thoughts and feelings.

7903. (*Chairman.*) Were anæsthetics used at that time?—No, and at any rate they were useless to be used for such experiments as Sir Charles Bell resorted to. He wanted to learn essentially the differentiation in the functions of the nerves as between those which convey sensation and those which convey the impulse to muscular action, and he could not have discovered what he was seeking to arrive at had he not made experiments upon animals without anæsthetics at the time of the experiments; and of course, as they necessitated the exposure of the spinal cord, they were necessarily of a most torturing and suffering character.

* *They are the micro-organisms of putrefaction—the bacilli of putrefaction and different species of "Proteus."—H. M.*

7904. About what date would that be?—I suppose about 1820. I forget the date of Bell's death.

(*Sir William Collins.*) He died in 1842.

(*Sir William Church.*) 1811 was the date of his celebrated pamphlet, in which I think I am right in saying he himself attributed his discovery to the experiments he was making in 1811.

7904a. (*Sir Mackenzie Chalmers.*) Chloroform was discovered about 1846?—There again I cannot say the exact date.

7905. (*Sir William Collins.*) The quotations that I put to you are dated 1823 and 1822?—I said I thought it would be about 1826. I had forgotten the date of Sir Charles Bell's death, but it was after he went to Edinburgh, and he went there in 1836.

7906. There is little doubt, is there, that Sir Charles Bell did make experiments, and that he attributed a great increase of knowledge to those experiments, and that he subsequently wrote rather disparagingly of experiments on living animals, because he felt that they were to some extent in conflict with this sense of morality?—Yes, but that he did attach importance to them and that he did find out epoch-making knowledge by experiments I suppose is beyond all question in your mind or mine.

7907. I am afraid at the present moment I am interrogating?—I put that merely as a figure of speech. I suppose it is beyond all question—everybody must admit the epoch-making importance of his discoveries.

7908. Do you think that they need to be repeated?—No. I have only quite recently been asking for further information before signing one of the certificates and schedules as to the necessity of making certain experiments on the spinal cord; because I should not sign the certificate if it was a mere matter of repetition of experiments and for the first-hand knowledge of the individual who wanted to make them. I consider that those experiments ought not to be repeated unless with some very special object in view.

7909. Might I put it to you that *à priori* physiology, which is the science of living things, and surgery, which has so largely to do with wounds, are both likely to be benefited by knowledge obtained by operations on living animals?—I think that both surgery and physiology will be advanced by operations on living animals.

7910. *A priori* it would be very surprising that, physiology and surgery being what they are, standing in the relation that they do to the science of life and the healing of wounds, operations on living animals would not be productive of some additional knowledge by their practice?—It would be very unlikely.

7911. Do you think that *à posteriori* you are able to adduce evidence that that *à priori* assumption has been justified?—Absolutely.

7912. But I understood your view, and that of the Royal College of Surgeons, to be that there should be a limitation by law placed on the practice of vivisection?—Yes.

7913. (*Dr. Gaskell.*) Might I ask one question with regard to Sir Charles Bell's work. Did not Bell publish later a certain amount of material; could you not say that he published some early papers and some later papers?—Yes.

7914. Is it not the early papers that we now consider valuable?—Yes.

7915. I mean that what is really lasting in Bell's work is that part which he himself attributed to experiments on living animals?—Certainly.

7916. (*Sir William Collins.*) Would you give us the date as to what you mean by later and earlier?—I would give the date of the earlier papers as those when he was working largely by experiments on animals; I forget the dates.

7917. Do you think that the papers which were published in 1823 were not valuable?—Certainly they were; but I think those were not some of his earliest papers; he went on working here in London till 1836, and then afterwards for four or five years in Edinburgh.

7918. In the earlier papers you would include the papers of 1823?—Yes, although in answering these questions I would not by any means cast, or seem to wish to cast, any want of appreciation upon the later papers, because he wrote upon surgery; for instance, he wrote several treatises upon surgery which were the result of his experience as a surgeon later in life. But my answer to your question was chiefly in reference to those more scientific investigations.

7919. (*Dr. Gaskell.*) What I meant simply was that those investigations of Sir Charles Bell, which we look upon so highly now, and which have lasted right away to this time, were all done or put forward by him at the time, and in consequence of the experimental work that he was doing?—Yes; and then the later ones that he wrote more especially had reference to his practice as a surgeon.

7920. (*Sir William Collins.*) You attach value to them all?—Yes, I attach value to those, too, of course.

7921. (*Sir Mackenzie Chalmers.*) You have brought before us a unanimous resolution of the Council of the Royal College of Surgeons?—Yes.

7922. The practical effect of that is that your Council unanimously support the existing law?—Yes.

7923. With a possible modification in a small detail?—Yes.

7924. Would you kindly tell us how the Council is composed; what is the number of the Council?—There are 24 members of the Council.

7925. Elected by whom or chosen by whom?—Elected by the Fellows of the College.

7926. (*Sir William Collins.*) Not by the members?—Not by the members.

7927. (*Sir Mackenzie Chalmers.*) The Fellowship of the Royal College of Surgeons is the highest surgical degree in England, I suppose?—We think it is the highest surgical degree anywhere.

7928. At any rate the Council represent what I suppose might describe as the best surgical opinion in England?—I think I may fairly say that it does, although I am a member of it and therefore do not speak personally.

7929. You are President?—Yes.

7930. I am speaking of the Council?—Yes.

7931. We may take it as expressing practically the great body of instructed surgical opinion in England?—Yes; and I may add that they are all, or nearly every every one of them, men who have spent a large part of their lives in teaching surgery as well as in practising it.

7932. I may take it, then, that your opinion is that experiments on animals in the past have been indissolubly mixed up with advance in the knowledge of surgery?—Yes.

7933. And, although it may be difficult to assign the proportions, you think it is absolutely necessary that they should continue for the future?—Yes.

7934. How long have you been practising yourself as a surgeon; you are still practising, are you not?—Yes; my house surgeon appointment was 1867 or 1868.

7935. Your experience as a surgeon goes over 40 years?—Yes.

7936. And during the whole of that time you have been continuously operating and in the operating room?—Yes.

7937. I want to ask you, if I may, one or two questions with reference to suggestions made by previous witnesses. Have you any opinion on this point? When an anæsthetic is administered is there any order in which you can put the disappearance of movement, disappearance of sensation, and disappearance of consciousness?—Disappearance of consciousness long precedes disappearance of movement.

7938. That is what I wanted to know. By consciousness I meant intellectual consciousness, as opposed to mere sensation of pain?—I take them all. Of course, really intellectual consciousness would go first; then the consciousness of pain would go long before the capacity for movement went.

7939. The movements might be even what you call purposive?—Purposive in this way, that they would be made to claw off the thing over the mouth, or made to kick away a hand or any restraining force over the knee—purposive to that extent.

7940. What I meant by purposive was that a person knowing nothing about anæsthetics, seeing an operation for the first time would think the patient was conscious?—Yes, and would think he was suffering horribly. I daresay many people would. I have seen a person, who has not known anything about what was going on, and has not been able afterwards to tell anything about what had been going on, having to be held down by six or eight persons during the latter portion of the administration of the anæsthetic.

Mr. H. Morris, P.R.C.S.

8 May 1907.

7941. Before the operation began?—Before the operation began.

7942. But absolutely unconscious?—Absolutely; they have not known the least thing of it afterwards.

7943. Does it vary with different individuals?—Yes, because some individuals will not struggle at all—they go off very quietly.

7944. Does it depend upon the nature of the anæsthetic to some extent at all?—It depends upon many causes. One always used to think, especially at Guy's, that people who had taken alcohol and people who had syphilis—I know it was the opinion of one of my teachers there, Mr. Bader—that syphilitic persons were amongst the most troublesome under chloroform, that they resisted the most; I mean people who had had syphilis comparatively recently.

7945. Now, may I take you to the next stage. During the operative procedure, may you, without recovery of sensation of pain, have any movements?—Yes. When a patient is absolutely unconscious to everything and is as still as possible, when you put the knife on the surface of his skin and begin to make an incision, he may struggle or turn, so that you may even yourself turn round and ask the anæsthetist whether the patient is fully under, and he will say, "Oh, yes, quite," and you know that he is.

7946. Are there any special nerves or muscles which are apt to contract and cause movements when the anæsthesia is still complete?—One of the tests that one often sees employed—it is a rough test—by a teacher showing a witness who is learning the administration, is to touch the conjunctive of the eye with the finger. We surgeons know that a patient may be absolutely insensitive to the touch of the conjunctiva with the finger, and yet give a very considerable writhe directly the operation is about to commence or is commencing round the fundament, round the anus. That probably is the last part of the body, so far as one knows, to answer to the anæsthetic.

7947. I want to take you again to the operation. In In what order does full consciousness come back (consciousness and sensation)? Is there any recognised order?—I could not answer that in a precise way, but the return of consciousness is sometimes very much delayed. Patients resist the touch of the hand long before they are conscious; they resist your moving a limb, or putting it into a certain position.

7948. Yet there is no sensation of pain?—No sensation of pain. The sense of pain will come back perhaps sooner than the sense of consciousness does; a patient will feel a prick of pain sooner than he will be able to hold an intelligent conversation.

7949. But would the power of motion come back before the sensation of pain?—Yes, long before.

7950. Is there any appreciable interval?—It would vary. May I give an illustration? How long a patient will be before he appreciates pain may be judged of by those rare and most unfortunate accidents which have occurred with regard to hot water bottles. A nurse perhaps has put a hot water bottle against the patient's side or against the patient's limb, and he lies against it perhaps for an hour or two, until, when the misfortune is discovered, there is a very considerable burn, which may end in a very considerable slough.

7951. That is after the patient has been put back to bed?—Yes.

7952. So that there is a very considerable interval before full sensation of pain and full power of feeling returns, after a strong and full dose of an anæsthetic?—There is a considerable interval elapsing before the patient will make an effort to move away from a hot water bottle, for instance, which is producing such damage that a very large slough will ensue.

7953. Although the patient is capable of making movements?—Yes.

7954. So far as your experience goes in the administration of an anæsthetic to animals, a full dose has been used?—Yes, I have seen that.

7955. For the reason which you gave, that the worst that can happen is that the animal dies prematurely?—Yes.

7956. Whereas in the case of one of your patients, it is important that he should recover?—Yes.

7957. Have you any opinion as to whether there is any difference in intensity between animal and human sensibility?—I have not.

7958. There are no data perhaps?—I have not any data except one's general experience of the indifference with which dogs and animals will go about wounded, as compared with a human being. A dog will run about, or a horse go walking about, with the whole of its entrails hanging out; and provided that it does not affect their limbs, they will go about and eat with the greatest indifference.

7959. A dog directly after a good fight shakes himself and shows very small signs of pain, as a rule?—Yes, if it is merely a flesh tear, or something of that sort, or even if a cavity is opened.

7960. We had some evidence here the other day of a medical anti-vivisection witness, who suggested that experiments on animals might be deceptive because unconsciously the experimenter hypnotised the animal. Have you anything to say with regard to that?—That hypnotism has taken the place of an anæsthetic, do you mean?

7961. No, she said, as I understood her, that the experimenter got the result from the experiment which he desired because he hypnotised the animal?—I fear that is a subject upon which I could not follow the lady.

7962. At any rate, you never attributed the success of any surgical operation to that force?—No. There have, of course, been things done on certain people by hypnotism.

7963. By Dr. Braid, of Manchester, for instance?—Yes.

7964. As regards amendments of the law, do you think it would be right, in granting certificates, that particular forms of anæsthetics should be prescribed; or do you think that they might be safely left to the operator?—I think it might be safely left as it is under the Act now.

7965. You do not think that any amendment is required there?—I do not think so at all. The Act specifically states that curare must not be used.

7966. As an anæsthetic?—An an anæsthetic, alone.

7967. It is used not as an anæsthetic, but as an adjunct to the operation?—Yes. I do not think that any further restrictions on that head are required.

7968. I suppose it is not likely that local anæsthetics would be used in experiments on animals in any severe experiment?—It depends upon what you mean by local anæsthetics.

7969. I was thinking of cocaine or eucaine?—I think it is possible that there might be cases where an injection of cocaine or urethane into the theca of the spinal chords might take the place of a general anæsthetic.

7970. For the purpose of operations below that place?—I am not sure that it need be limited to below the theca.

7971. Have you yourself in your own practice used local anæsthetics?—No.

7972. You always use a general anæsthetic?—Yes; but there have been many cases of surgical operations of moment reported as having been quite successful under an injection of eucaine and cocaine.

7973. Successful from the point of anæsthetisation?—Yes; so that that is a thing that might easily arrive.

7974. I do not know whether you have seen a pamphlet by Surgeon-General Sir James Thornton?—What is it entitled?

7975. It is "The Principal Claims on Behalf of Vivisection: A Refutation"?—No, I have not seen it.

7976. He has taken in a very convenient form—in alphabetical order—various heads, and has put in a most convenient and concise way the objections to vivisection. Some of those heads are purely surgical. I do not know whether it would be fair to read a short extract and ask you your opinion of it?—I shall be happy to hear it.

7977. On page 1, may I take the opening sentence? "Abdominal surgery had been seriously retarded by experiments on living animals. The following statement was made by Sir Frederick Treves in his 'Address on Some Rudiments of Intestinal Surgery,' delivered before the Midland Medical Society at Birmingham, and reported in the British Medical Journal, November 5th, 1898:—'Many years ago I carried out on the Continent sundry operations upon the intestines of dogs, but such are the differences between the human and canine bowel that when I came to operate upon man I found I was much hampered by

my new experience, that I had everything to unlearn, and that my experiments had done little but unfit me to deal with the human intestines.'" Have you any comment to make on that?—Of course, I am familiar with that sort of quotation, but I do not hesitate to say that my opinion is absolutely opposed to it as a general statement. I hold that abdominal surgery has been enormously advanced by experiments on animals, and I would go so far as to say that there are many operations, such, for instance, as that which I referred to in regard to the extirpation of the kidney, which I do not think any prudent and cautious surgeon would have undertaken, if it had not been for the knowledge which has been gained by experiments on animals.

7978. The next alphabetical head, which deals with surgery, is on page 4 on "Acupressure." I do not know how far you would agree with what he says there. "Lawson Tait, F.R.C.S., who conducted the chief experiments on this subject, writes: 'The conclusions of the experiments were quoted far and wide, were translated into foreign languages, and everything looked as if "acupressure" was to reform the art of surgery. But it did not; it speedily died out, and, I think, has been almost forgotten. The explanation of this lay in the simple fact that the closure of a dog's artery is altogether a different process from that seen in the human vessel, and my experiments were not only needless, but they were absolutely misleading.'" Have you any comment to make upon that paragraph?—With regard to acupressure, I should say that I remember the time when it was introduced and when it was very considerably tried, and I should say that in many instances it was a better method of controlling hæmorrhage with safety than the ligature was. I remember when it was used for amputations of thighs, and so on; and it used to produce an exceedingly good effect. But we have now safer, more certain, and more convenient methods of controlling primary hæmorrhage after amputations, etc., than by means of these acupressure needles. Acupressure is never employed now for that reason.

7979. It has been superseded by a better method?—Yes.

7980. It was an improvement on the old method?—Yes.

7981. But it has now been superseded by newer and better methods?—Yes.

7982. Then he controverts exactly what you said in your *précis* about antiseptic surgery. I do not think I need trouble you with that, because you have given your evidence, and it is in opposition to Sir James Thornton's view. Would you kindly look at page 7—"Blood-pressure Experiments"—and would you say whether you agree with this passage quoted from Dr. Macaulay: "For practical application in medicine the numerous experiments made since the time of Hales are quite useless. The force of the heart, for example, varies in the animals inspected, and under different conditions; and the variations are infinite in different persons, in various conditions of age, strength, and state of health. The general estimates may be interesting as facts for philosophical statement, but are useless with any view of applying such experiments to use in maladies either of the sanguineous or nervous system. More useful information can be obtained by observing the force of the heart as indicated on the delicate dial of a balance-chair than from all the experiments of vivisectors." Will you make any comment on that that you think fit?—I have not had time to read these extracts and think them over in all points, but as I read this through here, I should suppose that the writer of it had very little experience of the experiments and results of experiments which have been made with regard to many drugs.

7983. Do you know the writer by name?—No.

7984. The writer is apparently Dr. Macaulay, in his Prize Essay in 1881. Do you know anything about Dr. Macaulay?—No, I cannot say that I do.

7985. He is not a known authority?—I do not know him.

7986. Sir James Thornton adopts it, I presume?—I was thinking that anyone who wrote it, or adopted it, had probably not had very much experience of experiments and the results of experiments on animals, as I mentioned.

7987. He next deals with brain experiments. Sir Victor Horsley will tell us about them?—Yes.

7988. Now, may I ask you to look at page 17, because that touches your evidence. "Kidney Removal. It has been asserted that the operation for removal of a diseased kidney was devised through experiments on dogs, but this claim cannot be sustained, as the operation in question is very ancient, and was done in the time of Hippocrates. It has long been known to pathologists that a person may live with one kidney practically useless; no experiments, therefore, were required to prove it, especially as there have been rare instances of congenital absence of one kidney." You have already dealt with this?—Yes, I have referred to it in my *précis*.

7989. Would you like to make any comment on that passage?—It is quite true that experiments have been made many years ago. I referred to them in some little detail in some lectures* I gave some years ago. Simon probably was aware of them—it is possible that he was not; but I think that even if he had been aware of them, they were not of such a date and of such a character that he would have felt justified in basing upon them the operation which he did upon the first patient of his.

7990. And since his operation, it has become an operation carried out from time to time?—Yes, nearly every week, I should say.

7991. It is an operation you have done yourself?—Very many times.

7992. Then there is rather a long attack on Pasteur's anti-rabic inoculations. Sir James Thornton suggests an alternative treatment, such as the Buisson baths. Have you any opinion to express upon that?—I have a great opinion of the anti-rabic treatment, but I know nothing about the other.

7993. If a patient of yours was bitten by a dog that you believed to be mad, would you take the responsibility of advising him to undergo Pasteur's treatment?—Yes, certainly.

7994. Without hesitation?—Without hesitation. But that is assuming that it was actually a rabid dog.

7995. I say a dog reasonably believed to be mad?—Yes.

7996. (*Dr. Gaskell.*) I wanted just to ask you whether in conditions of light anæsthesia, such as a dentist uses, and so on, you may not often get movements, and even cries, and the patients afterwards say that they felt no pain?—Yes.

7997. Not only movements, but actual cries at the moment when the operation is done?—That is so.

7998. I have seen a case with Sir George Murray Humphrey at Addenbrookes Hospital, in Cambridge, in which he removed a large fatty tumour. While the operation was going on, the patient came round, and conversed with me, and said he was very comfortable and felt no pain, although he knew exactly what was going on; and after the operation he jumped off the table and walked off to the ward by himself. Have you ever seen anything of that sort during anæsthesia when the patient apparently was entirely conscious and yet felt no pain?—No, I do not recall a parallel case.

7999. But have you not ever heard that the patient has said afterwards, "I knew what you were doing"?—Yes, I have heard that very often.

8000. And that means a certain amount of consciousness?—I suppose the patient would even have been conscious. I might perhaps give you an instance. At the end of an operation, perhaps it occurs to me before putting a dressing on the wound that I had better put another suture, another stitch, into the wound. The patient is now coming round, and gives a little cry; and afterwards, when he has been asked whether he cried because he felt the pain, he has forgotten all about it if he had felt it.

8001. So that really one may take it that pain is one of the first things to go?—Yes.

8002. Even although there is still a certain amount of consciousness left in many cases?—Yes.

8003. Another point that I want to ask you about is with respect to manual skill. The Act says that no one shall be licensed under it for the purpose of acquiring manual skill?—Yes.

* "*The Origin and Progress of Renal Surgery*"—*Hunterian Lectures, 1898.*—*H.M.*

Mr. H. Morris, P.R.C.S.

8 May 1907.

8004. Then I understood you to say that in the case of surgeons it might be advisable sometimes for them to perform an operation on an animal before performing on a human being?—Yes; but I would not say that from the point of view of his acquiring general manual skill, but from the point of view of learning the technique of some particular operation.

8005. But that at present is illegal, is it not; the Act would forbid you to obtain that necessary skill?—Yes.

8006. Would you not, therefore, as representing the Royal College of Surgeons, like to see the Act altered in that respect?—I am not quite sure whether the Act does forbid it.

8007. To obtain the technique, I said?—Yes, not manual skill; that is forbidden. To give an illustration: Supposing you are going to cut a cancer out of the bowel, and are going to remove it altogether; you have to cut the bowel above and below the site of the cancer widely, so as to take it all away; then you have to join those two ends of the bowel up. How are you going to do it? Will you stitch up one end entirely and graft the other end into the bowel above, or will you join them end to end? That is the kind of thing I meant; and you can find it out by experiments on animals; and you might find that out, I think, under the Act, under licence and Certificate B. That is a thing of which it is very desirable that we should be able to learn the technique in that way, or to test it in that way. But that is not what I thought you meant. I think the Act means that experimentation is not to be employed for learning manual skill on the part of a young surgeon.

8008. It does not say anything of the kind; it says manual skill?—I always read it in that way.

8009. One final question with respect to demonstrations. Have you read "The Shambles of Science"?—Oh, yes.

8010. Do you consider that for advanced students who are likely to be teachers of physiology, and are likely to hold teaching positions in some way in connection with medicine, the kind of demonstrations spoken of there ought to be forbidden?—I cannot call to mind all those demonstrations.

8011. They were demonstrations showing comparatively new discoveries in physiology; not demonstrations that you would give to young students first coming in to study physiology, but deliberately given as showing the latest results of experimental work in physiology?—I think that those who are going to be practical teachers of physiology ought to have an opportunity of witnessing many experiments, and perhaps doing experiments, which are not necessary to be shown to ordinary students—if that is your point.

8012. Yes. It has been said that those experiments ought not to be allowed, and hardly are allowed under the Act?—I cannot answer that question, because I do not know what those experiments are.

8013. I mean those experiments which are described in the "Shambles of Science"?—I have not got them sufficiently in mind.

8014. But they are experiments for advanced students showing the newest things in physiology?—I think, as I have said already, that many experiments ought to be permitted to those who are going to teach and practice physiology which ought not to be permitted, or ought not to be shown,, to ordinary general students.

8015. Which would be useless for ordinary students?—Yes.

8016. (*Mr. Tomkinson.*) You spoke of the valuable results of surgical demonstrations in regard to observing the action of the heart and entrails?—Those we call physiological experiments; they are not surgical. They do not come into any part of either surgical teaching or practice.

8017. I wish to ask you, would the action of those organs be affected by the fact of the animal being under anæsthetics?—Not sufficiently to prevent the observer getting a true and accurate idea of what goes on.

8018. With regard to the completeness of anæsthesia and the use of curare, you deprecate the use of curare alone?—Yes, I do; we do not know absolutely for certain everything about it.

8019. Do you think that, administered with chloroform or ether and other real anæsthetics, there may not be a danger of the animal being powerless through the effect of the curare, and yet the anæsthesia would be imperfect at the time?—I do not think so at all. I am aware to what you refer, of course—that the animal being under the influence of curare cannot move even though it may suffer; but I think, from the way in which I have always seen and have always heard that chloroform or ether is administered, there is not the least fear of that.

8020. You are absolutely satisfied in your own mind that complete anæsthesia is always aimed at most carefully and in your opinion secured?—Yes, I do think so; and certainly I have always seen it.

8021. Little has been said about the paragraph in your *précis* on the question of shock. May I ask whether you have seen that pamphlet giving a description of 16 experiments by Dr. George Crile upon animals?—Yes, I have read it a long time ago.

8022. The pamphlet excited a good deal of attention and, I may say, horror among a great many people, from the tremendous severity of the operations to which the dogs were subjected?—Yes.

8023. In your opinion were the results, from any point of view, at all commensurate with the severity of such operations on the observation of shock or the effect of shock?—I hardly feel that I can form a just opinion about that. I did not like many of the experiments that were performed, but I would not like to express a definite opinion.

8024. You hardly feel prepared to justify them altogether?—No; and I would hardly be prepared to say that they were not desirable to have been made once, but I certainly think that such things ought not to be repeated for the sake of repeating them.

8025. Provided that complete anæsthesia can be secured, I suppose you would be opposed and object to any really painful experiment without it?—I would not go quite so far as that; because, if I may again refer to the experiments which were made by Sir Charles Bell many years ago, it is possible that some investigations involving more or less pain might be very desirable; but as a rule I should certainly say so.

8026. Could you express any opinion as to whether from the moral point of view it would be justifiable to inflict really painful experiments for possible results in search of alleviating human suffering or the prevention of it?—That is a matter upon which of course each individual will have his own opinion. As a great lover of dogs, and as a person very desirous of saving animal suffering, I should still say that I thought that from the moral aspect it was quite justifiable.

8027. (*Dr. Wilson.*) There is only one question that I should like to put to you. Are you of opinion that a very severe and prolonged operation can be performed on an animal under narcosis alone, under morphia for example, or paraldehyde or eucaine, an operation involving the opening of the abdomen, the thorax, and so on, to continue, say, for an hour or an hour and a half or longer?—Under the conditions suggested by Sir William Church I certainly think that an operation could be performed under morphia alone without the animal feeling any pain.

8028. You think that the animal could live even through that period if it had a poisonous dose?—I think so.

NINETEENTH DAY.

Wednesday, 15*th May* 1907.

PRESENT:

Sir W. S. Church, Bart., K.C.B., M.D. (*in the Chair*).

Colonel the Right Hon. A. M. Lockwood, C.V.O., M.P.*
Sir W. J. Collins, M.P., M.D., F.R.C.S.
Sir J. McFadyean, M.B.
Sir M. D. Chalmers, K.C.B., C.S.I.
Mr. A. J. Ram, K.C.
Mr. W. H. Gaskell, M.D., F.R.S.
Mr. J. Tomkinson, M.P.
Mr. G. Wilson, LL.D., M.D.
Captain C. Bigham, C.M.G. (*Secretary*).

Major Leonard Rogers, M.D., F.R.C.P., I.M.S., called in; and Examined.

Major L. Rogers M.D., F.R.C.P., I.M.S.
15 May 1907.

8029. (*Sir William Church.*) You are a Fellow of the Royal College of Physicians and Professor of Pathology at the Medical College, Calcutta?—Yes.

8030. And you are a Major in the Indian Medical Service?—Yes.

8031. You consider that our present knowledge of the physiological action, and of the antidotes of snake poisons, is founded entirely on the results of experiments on animals?—Yes.

8032. Will you tell us on what grounds you base that opinion?—The most important early experiments are those of Sir Joseph Fayrer and Sir Lauder Brunton on cobra venom, which showed that the cobra venom kills by producing paralysis of the respiratory centres, and has subsidiary actions, but that that is the principal action and the primary cause of death. As the result of those experiments, they carried on artificial respiration, and they found that they could keep animals alive for a large number of hours, even up to twenty-four hours after paralysis of respiration had taken place. And subsequently, a further Commission worked in India, and suggested the practical value of this method, and they succeeded in recovering a few animals after many hours of artificial respiration. And there have been a few cases on record, one in Ceylon in particular, where this method appears to have been successful in saving the lives of human beings who had been bitten by cobras; but, unfortunately, it only works if the dose of cobra venom is comparatively small, only just a lethal dose, but if the cobra injects several times a fatal dose it is not possible to recover the patient by that method.

8033. Have further experiments shown that it is probable that intravascular clotting also is part of the cause of death, besides the paralysis of respiration?—That is, in the case of Russell's viper, and viperine poisons. The viperine class of poisons have a totally different action from that of the cobra class, that is the poisonous colubrines. It was first shown by Professor C. J. Martin, now of the Lister Institute, that one of the snakes in Australia caused intravascular clotting, and he suggested that this was probably the physiological action of the viperine class; and it was afterwards shown by Lamb in Bombay, that Russell's viper does cause death in that way. Four years ago I investigated this subject at the physiological laboratory at the London University with Dr. Waller, and I tested vipers, both Russell's viper of India, the rattlesnake of America, and the African puff adder, and I found that, in addition to this intravascular clotting you also got paralysis of the vaso-motor centre, and that that is the most essential cause of death in the case of viperine snake poisons. I also found that it could be counteracted to a considerable extent by the action of drugs, especially adrenalin, which contract the vessels and so counteract the fall of blood pressure. I published the experiments in a paper read before the Royal Society, and illustrated my point with tracings. So that our knowledge of the viperine poison's physiological action is also due entirely to experiments on animals.

8034. You wish also to refer to some experiments of Lille and Sir Thomas Fraser?—Yes. The next point in the action of snake poisons is the question of the action of antivenins, first discovered by Calmette of Lille, and independently by Sir Thomas Fraser. They found, as the result of repeated inoculation of cobra venom into animals such as horses over a period of many months, taking usually eighteen months, that they were able to produce a powerful serum or antidote in the blood of the infected horses, which has a definite specific action against the cobra venom; so that after injection of the cobra venom into an animal it is possible to save that animal's life by the injection into a different part of the body of a proper dose of the antivenin. In some experiments which I have done on this question, too, I found that the results are very much better if the antidote is injected intravenously. If the anti-cobra serum is injected intravenously it has exactly the same action upon the system of the animal that it has if mixed with cobra venom before injection; but if it is injected subcutaneously, it is absorbed more slowly, and does not act so efficiently. There is one difficulty with regard to the practical application of this treatment, which is, that the serum made from cobra venom does not act at all against the venoms of the viperine class, which have a different physiological action; and, further, the antivenin made from cobra venom only has a slight action against other colubrine poisons, such as the krait or the hamadryad.

8035. Therefore, although the antivenin has a decided protective influence, it is not practically of very great use?—No.

8036. Because it is not at hand?—It is not on hand, for one condition; you seldom have both the antivenin and the syringe on the spot; and even if you have it really requires much larger doses than are usually given.

8037. (*Sir Mackenzie Chalmers.*) And a very skilled operator?—Yes.

8038. No village man could do it?—No, I do not think so. There have been a number of cases reported where it has apparently had a good effect.

* *Col. Lockwood came in late during the sitting, and Sir W. Church therefore remained in the Chair.*

Major L. Rogers, M.D., F.R.C.P., I.M.S.

15 May 1907.

8039. Where a doctor happens to have been near?—Yes. The best example was the case of Captain Lamb. He was investigating snake poison in Bombay and he was bitten by a cobra in the thumb, one fang entering. They were testing antivenin at the time, and the antivenin which they had they found was not strong enough to be of much use, so that they had to send for some more. It was an hour before they got an efficient serum, and by that time Captain Lamb was beginning to show symptoms of drowsiness and early symptoms of cobra poisoning. After an injection of the antivenin he recovered perfectly well with some local sloughing, which you always get after such poisoning. That is a definite case where antivenin appears to have saved life.

8040. (*Sir William Church.*) How long ago did you take up the subject?—I was working first at the sea snake poisons in Calcutta, in 1901, when I found that they were very poisonous, and that their venom had the same action as the cobra venom. Then when I was in London in 1903 I was working at the physiological action of the sea snakes and the viperine poisons which I have mentioned; and then Sir Lauder Brunton suggested to me the carrying out of experiments to test the value of the method he had previously suggested of a local application of permanganate of potash by incising the seat of the bite, or the injection of venom and rubbing in the crystals.

8041. Sir Lauder Brunton and Sir Joseph Fayrer, I think, found that mixing a solution of permanganate of potash with cobra venom destroyed its activity?—Yes.

8042. And then did he request you to continue the experiments with permanganate of potash?—He requested me to continue the experiments. He had previously published the suggestion of making the snake lancet, and it had actually been made; but as it had not been thoroughly tested and proved, it had not come into practice; and he asked me to take the matter up at that point. The first thing I did was to test the action of permanganate of potash on a number of different venoms, as it was previously only known that it destroyed cobra venom. I tested it against all the Indian colubrine poisons, the krait venom, the hamadryad and the banded krait, and the sea snakes, and also against Russell's viper of India, the rattlesnake of America, and the African puff adder; and I found that mixing a strong solution of permanganate of potash with any of these venoms would destroy the venoms in almost the same weight as the permanganate of potash; so that it has a very powerful action. It appears to act by oxydising these substances, which are all albumoses, which are an unstable form of albumen, into a harmless substance.

8043. Do you know at all why Sir Lauder Brunton and Sir Joseph Fayrer did not carry on their experiments with permanganate of potash?—I do not know the details of it. Sir Lauder Brunton told me that it was owing to the passing of the Anti-vivisection Act that his experiments were stopped—he was unable to go on. At that time he was trying injections of a solution of permanganate of potash as a form of treatment; but that apparently is not an efficient method of using it. What he told me was that his experiments were stopped by the passing of the Act. Then next I started carrying out experiments on animals as nearly as possible under conditions in which the permanganate of potash would be used in actual practice. I used rabbits and cats.

8044. You say that you carried out the experiments on animals as nearly as possible under the conditions in which the permanganate of potash would be used; but these animals, I gather, were under an anæsthetic?—They were chloroformed. There was a difference in that point. The animals were all chloroformed, then a measured dose of cobra venom was given in accordance with the weight of the animal, so many lethal doses, or, rather, so many times a fatal dose. The injections were made a little above the foot. Ordinarily snake bites are on the hand or foot, as a rule. After the measured time had elapsed, varying with the different experiments, a ligature was applied above the seat of the injection, in order to stop the circulation. An incision was then made at the seat of the injection with a small lancet—the actual lancet which is now being sold in India, and at the seat of the injection within 30 seconds I found that there was always a small blood-stained effusion, which is of practical importance, at any rate, as it shows the exact seat of the venom; a few permanganate crystals were then poured into the wound and rubbed in until the wound was completely blackened. This took one or two minutes. The ligature was then immediately removed on the supposition that the poison had been destroyed by the application of the permanganate of potash. The cats were then allowed to come round—I had reason, of course, for doing that—and kept from five days to a week. They appeared to suffer no pain; in fact, the only difficulty I had with them was that they all wanted to be petted at the same time if I went to see them. As the result of the experiments, I found that after the injection of ten times a fatal dose of cobra venom I could save the animal by operating 30 seconds afterwards. That is about the time it takes to apply the ligature if a person is bitten in a limb. I lost one animal after the injection of five times a fatal dose (it was the first animal done), the application not having been efficiently carried out as in the latter case; but its life was very greatly prolonged as compared with the control animal injected with the same dose without the treatment. Then I used decreasing doses of venom at longer intervals, and I have now worked up to getting a recovery in the case of a cat not treated until half an hour after the injection of a double lethal dose.

8045. (*Sir Mackenzie Chalmers.*) By treating, do you mean the ligature?—The ligature and the permanganate treatment.

8046. They are contemporaneous practically?—Yes.

8047. When you talked of 30 seconds, what did that mean?—That means the application of the ligature.

8048. The other would be within half a minute?—Yes, as soon as possible. The time limit is the time when the ligature is applied which gives you time during which there has been a chance for the absorption of the venom.

8049. In the case of a human being, could you apply a ligature?—Yes, as a matter of fact, the natives almost invariably do it. Similarly I tested with Russell's viper as a type of the viperine class, and there I have got recoveries up to five times a fatal dose, which is more than any viper I know of can inject, judging from the amounts I have obtained from these snakes, in proportion to the weight of a man. That is the experimental basis of the method.

8050. (*Sir William Church.*) And this method has been successfully applied to human being?—Yes. Now with the printed instructions giving directions for the use of the lancet, supplied with each lancet, I ask to have reports sent to me; and I have received a number of reports during the last three years, which I found it necessary to classify in two different classes. In judging of the action of any remedy in the case of snake bite there are a great many fallacies to be avoided. In the first place, the patient may not have been bitten by a poisonous snake; and in the second place, he may not have received a fatal dose; consequently it is owing to this that so many remedies have been brought forward as cures for snake bite which have been found experimentally not to be efficient. In order to try and get absolutely accurate figures I have taken in my first class only the cases in which the snake has been killed and identified as a poisonous one, and in which there were definite fang marks where undoubtedly the patient had been bitten by a poisonous snake.

8051. May I ask in what way the snake has been identified as a poisonous one?—The snake has been identified as a poisonous one by the hospital assistant, in some cases by qualified medical men. Many years ago as the result of Fayrer's work the Government of India provided coloured plates of different poisonous snakes to all the dispensaries in India; so that these men are trained to recognise these snakes, and I think with the great majority of these cases certainly the identification has been undoubtedly accurate. I cannot vouch for it personally, but that is as near as I can get.

8052. (*Sir Mackenzie Chalmers.*) You mean that the snake is killed and brought to the dispensary?—The snake is killed and brought to the dispensary and identified by the assistant surgeon, who has been trained and has these coloured plates at his disposal.

8053. (*Sir William Church.*) The identification of a poisonous snake is not a difficult matter, is it?—No, not to these men who have the coloured plates, and have been trained to it.

8054. No non-poisonous snake has got the character

istic fangs, has it?—No, the fangs are quite definite, and then, again, in nearly all the cases I have got a definite note of there were two definite fang marks, punctures which would not be produced by anything but a poisonous snake. Among these 14 cases where the snake was killed and identified, nine were cobras, three Russell's vipers, and two kraits, these being the commonest very poisonous snakes in India. The large number of cobra cases is important, because in measuring the amount of cobra venom that one can obtain from a freshly-caught cobra, the amount averages ten times a fatal dose for a man; so that it is exceedingly unlikely that many of these cobras can have injected less than one fatal dose, and it is very unlikely that more than at any rate one or two of these patients had not received a fatal dose of venom. Among these 14 cases there was one death, and this was a woman, who was brought to the hospital eleven hours after the infliction of the bite, when she was quite moribund. She had been bitten at 3 o'clock in the morning, and was brought to the hospital in the middle of the next day; and in that case, of course, no treatment could be expected to have any effect. On the other hand, there was one case of a cobra bite in which the patient was not treated until four hours afterwards, when definite symptoms had set in, and from my experience of experimental work I know that any animal which shows symptoms within four hours of injection of cobra venom will always die; so that I have no doubt that this man's life was saved by the treatment. It is also well known that an animal may recover after well-marked symptoms have set in; if you give just a fatal dose, or rather a dose which is just not fatal, the animal may actually remain paralysed for 24 or even 48 hours, and still recover. So that it does not follow that after symptoms have set in you may not save your patient; it entirely depends upon whether a fatal dose has already entered the circulation; if not, by destroying all venom locally which is not absorbed, you prevent a fatal dose being absorbed, and so may save your patient after symptoms have set in.

8055. (*Mr. Ram.*) In that case, of course, the symptoms showed, I understand, that beyond all doubt the cobra was the cause of the bite?—I think so, from the description.

8056. There is nothing to show, I suppose, whether the dose was a fatal dose or not?—Nothing more than the fact that the symptoms had set in within four hours; and I know that in animals if symptoms set in within four hours they never recover. If you give a non-fatal dose you often get no symptoms in less than 12 hours.

8057. (*Sir Mackenzie Chalmers.*) What is the ordinary period within which symptoms set in in the case of the cobra?—It depends entirely on the dose. If the cobra injects its full quantity of ten times a fatal dose, you get symptoms within half an hour, not, I think, much earlier; so that does give you ample time.

8058. You have half an hour's grace?—Yes.

8059. (*Mr. Ram.*) In the worst cases?—Yes.

8060. (*Dr. Wilson.*) Had the natives applied the ligature in these cases before they were brought to you?—Yes, in a number of them they had. In a good many of these cases the ligature had been applied.

8061. Do you know in what proportion?—I have notes of some; I have not been able to get full details of all the cases. I have corresponded with regard to them so far as I could. I have four cases here where the ligature was applied at once.

8062. Before they came to you?—Yes, before they were brought for treatment, and that, of course, makes it much more favourable.

8063. (*Sir William Church.*) In the 34 cases in which the snake was not killed and identified, was there evidence of any of those being bitten by a poisonous snake?—In a number of those cases it was reported that the snake was actually named as a cobra, but the snake was not killed; so that I thought it better to exclude them.

8064. (*Sir Mackenzie Chalmers.*) The natives know the cobra very well?—Yes, but I wanted to be on the safe side.

8065. It is not an easy snake to mistake for any other?—No. One difficulty is that even after a cobra has bitten a native they will not kill it very often; so that a number of cases in that 34 were certainly bitten by cobras, but as the snake was not killed I put them in the other class.

8066. (*Sir William Church.*) Six of those cases were fatal?—Yes. One was not treated till nine hours afterwards, and three others from four to six hours after; but one observer reported three cases treated two hours after which died. That is the only record of any case which has failed that I know of; but the same observer reported 20 successful cases.

8067. You go on to say that it is unlikely that such a large number would have been saved—that is, 24 out of 30—without the use of the permanganate locally applied; and then you go on to say that in some of these cases it was successfully applied by persons without any medical training?—That ought also to have applied, of course, to the first series. It applies to both series.

8068. It applies to all?—It applies to all. There was one case of a Russell's viper treated by a European some thousand miles away in the north of Siam.

8069. You do not think that without your experiment on animals it would have occurred to anyone to use this treatment?—Sir Lauder Brunton had actually had the lancet made, and had described it in his book on "Therapeutics."

8070. He arrived at it in seeing the effect of mixing permanganate of potash with cobra venom before he injected it into the animal?—Yes. There have been thousands of remedies brought forward supposed to have been used in cases, but that evidence is so absolutely unreliable that without the experiments, I think, it would have been impossible to establish any form of treatment; and this treatment was undoubtedly established as the result of experimental work on animals.

8071. Could you inform the Commission at all what the mortality from snake bite in India is?—About 20,000 cases are reported every year in India, and 10,000 of these, just about half, occur in Bengal alone.

8072. (*Mr. Tomkinson.*) Fatal cases?—Yes, those are really fatal cases. Of course, you cannot look upon these as absolutely reliable statistics, but I think they give a very fair idea.

8073. (*Sir Mackenzie Chalmers.*) And year by year they are very much the same?—Year by year they are very much the same.

8074. (*Sir William Church.*) You do not think that a large number of deaths not due to snake poison are put down in the returns to snake poison?—I do not think so. I should think it is more likely the other way, because I know from experience that over 90 per cent. of deaths are returned as fever, and I have known any disease returned as fever. The ordinary tendency for the village man is to return everything as fever; in fact, I have myself met with cases of snake bite recorded as fever.

8075. So that a sudden and unexpected or suspicious death is not put down to snake bite, which has often been stated to be the case?—That is a conceivable thing; but I think, taking the whole cases, it is more likely that they are underestimated than overestimated.

8076. (*Mr. Ram.*) Who makes the return?—The return is made by the Headman of the village in different parts of India.

8077. Is he bound to make a return?—Yes.

8078. Of every death?—Yes. He is not a medical man.

8079. (*Sir Mackenzie Chalmers.*) He is a registrar?—Yes, in different parts of India he is sometimes called the Chokidor.

8080. (*Sir William Church.*) Can you give the Commission any idea of the amount of loss of life caused by snake bite?—I do not know the exact figures, but I know that there are many thousands a year returned as due to snake bite.

8081. Perhaps some members of the Commission would like to ask you some questions with regard to snake bite before we go on to the second part of your *précis*?—If you please.

8082. (*Sir William Collins.*) Do I rightly understand that the nature of the poison in these cases of snake bite is a chemical one?—What do you mean exactly by chemical?

Major L. Rogers, M.D., F.R.C.P., I.M.S.

15 May 1907.

8083. Is it due to an organism?—No; it is chemical in that sense.

8084. And I think you said that it was due to albumoses?—Yes.

8085. Are they substances which are destroyed by oxidation?—Yes.

8086. And is the principle of the utilisation of the permanganate of potash to act as an oxydising agent upon the chemical poison?—The permanganate of potash was first used before the nature of the poisons was known. In Sir Lauder Brunton's time the composition of snake poison was not generally known. That is my suggestion, that it acts as an oxydiser.

8087. It is the essential principle of Condy's Fluid, is it not?—Yes.

8088. Are all cases of snake bite by poisonous snakes in the human subject fatal?—No, by no means.

8089. Can you give us any idea what proportion of cases are fatal?—It is very difficult to get evidence of that.

8090. Assuming a bite, by an admittedly poisonous snake, in a human subject, what proportion of cases would be fatal?—I should say a very large proportion, certainly 75 per cent.

8091. Do you think we might say that 25 per cent. would recover?—I do not think necessarily so. I say that at least 75 per cent. die, and probably a great many more. I am very anxious not to exaggerate.

8092. And even if symptoms have supervened may recovery occur?—Yes.

8093. Did I rightly understand you to say that a ligature was the regular mode of treatment?—The natives use a ligature almost invariably—very often indeed.

8094. Do you regard the ligature as a successful mode of treatment?—Not by itself; it would delay death, but would not save a man's life.

8095. Do you think that in any case it would preclude a fatal result?—I do not think so. I tried an experiment on it once by ligaturing the wound and opening it again after a time, and letting a little poison in at a time.

8096. Did you try a series of control experiments with the ligature without injection, and a series with the ligature with injection?—Yes; it delays death, but I never got any result of preventing death.

8097. Have you published those results?—No; they were done at Rawal Pindi the first year I was out. I did not get any practical results, so that I did not publish them.

8098. You are in the Indian Medical Service?—I am.

8099. Did you make reports annually to the Government?—Those were entirely private experiments of my own; I was in military employ, and I did them in my spare time.

8100. Have you in the course of any official report made a reference to these experiments?—No; all my papers have been published either by the Royal Society or in the medical journals. Most of my work was done in my spare time, mostly when I was on leave.

8101. How many cases of bite from a poisonous snake have you seen yourself in human beings?—One.

8102. Was the remedy applied in that case?—The remedy was applied by me in a few minutes, and the patients had no bad systems—that was in Calcutta.

8103. And in the cases which you have brought before us—this series of fourteen cases with one death—was the poison from the snake tested upon animals?—No, certainly not. How could it have been? There was no opportunity of doing so. These cases have all been reported to me by different medical men in different parts of the country, and there was no reason for doing it. It is all a question of how much the snake injected. If you make it bite another animal, it may have exhausted its venom, and you will prove nothing.

8104. You think it would be superfluous?—Absolutely. If a snake has bitten an animal and has exhaused its venom, if you made it bite a dog, and it did not kill it, that would not prove that it had not killed a man in the first instance.

8105. I should have thought that the experiments might have been considered of value; but I am quite prepared to take your opinion?—If I had been on the spot to do it, I should have been very glad; but there is no doubt how very uniform the strength of cobra venom is.

8106. Do I correctly understand that in your second series of cases there were 34 cases and six deaths, as against 14 cases and one death in your first series?—Yes, so it happens.

8107. To what do you attribute the excess of mortality in the second series as against the first?—Because in the second series there were three cases which were not treated for four hours or more after the bite; and but one case occurred which was treated at a later time than that in the first series.

8108. But the distinction between the two classes is, that in the first the snake was identified, and in the second it was not?—That is one distinction; but there is the further distinction which I have mentioned, that in two fatal cases in the second series the patient did not come under treatment till much later than those which recovered in the first series, which makes an essential difference in the mortality.

8109. Has the Government of India adopted the method of using the permanganate of potash?—When the method was first brought out they declined to adopt it on Sir Joseph Fayrer's recommendation; but since these results have been published they are now widely distributing the lancet in every village in several provinces, having been convinced of the utility of the method.

8110. At the public expense?—Yes.

8111. Is it being sold as well as supplied?—Yes, over 7,000 lancets are sold by one firm in Calcutta. Every European going shooting, and that sort of thing, practically invariably takes one.

8112. How long has that distribution been going on?—It is only three years ago since those results were published, and it is only last year that the Government have taken it up extensively. The previous distribution was entirely by sale through chemists.

8113. Is it too early yet to notice whether it has had any effect upon the mortality returns?—Certainly it is much to early.

8114. Do you institute any comparison between the method of Calmette and this method of permanganate?—The two should be combined. This is practically a method which applies to every kind of snake. Calmette's method does not, because the antivenin which is made for cobra is only useful for cobra. An antivenin has been made for Russell's viper recently, but it will only work for Russell's viper; and, further, the amount of sera required is very large, larger than is often practicable; but if the permanganate treatment is being used to destroy all the venom remaining locally at the seat of injection, then the use of antivenin becomes much more likely to save life, as it would have only to act against a much smaller amount of venom; so that if you happen to get a patient who has just absorbed a fatal dose and so that the permanganate treatment would be too late to save life, by destroying all the venom remaining locally by the permanganate method you could then save that patient's life by a comparatively small dose of the antivenin. So that the permangante mode really makes the antivenin one much more practicable.

8115. Then by the combined method, the local use of permangante crystals and subsequent injection of Calmette's serum, would you be able to say within a certain number of hours subsequent to the onset of symptoms, that you might deal with perfect success with a case of snake bite?—I think you could if you identified your snake, so that you knew what serum to use, and if you had got that particular serum available, which unfortunately is seldom the case.

8116. There is no polyvalent serum?—Not yet; they are making one for both cobra and Russell's viper at the Pasteur Institute at Kasauli.

8117. I suppose that the production of these sera is the result of experiments on animals?—Entirely.

8118. Seeing that snake poison is not due to an organism, by what mode is the antitoxin or vaccine or serum prepared?—It is prepared by injecting the measured doses of the venom which is obtained from the snakes and then dried, and in the dried condition it can be kept for 30 years or more without losing its strength; then measured quantities of this are injected, beginning with much less than a fatal dose and gradually increasing it until many times a fatal dose can

be injected into the animal; and this causes the production of the antidote in the horse's blood, just as after the injection of the diphtheria toxin in the case of the antidiphtheritic serum.

8119. Then is the antitoxin obtained from a horse by injection of an attenuated dose of the original poison?—Beginning with an attenuated dose, going on to very large doses.

8120. (*Sir Mackenzie Chalmers.*) The animal becomes tolerant as you go on?—Yes, and you may give a hundred times a fatal dose.

8121. (*Sir William Collins.*) It has been stated in the course of evidence before the Commission that the injection of a solution of permanganate of potash was not efficient?—It has not been found so.

8122. Whose experiments were those?—Sir James Fayrer and Sir Lauder Brunton's experiments were the original ones, and some have been done by other people as well. There was a paper published by Brieger a short time ago, but he used a very weak solution.

8123. Do you mean that the animal died in spite of the use of the injection?—Yes. Another great disadvantage of the injection is that you must have a syringe, which is not available under ordinary conditions; whereas the snake lancet is an inch long and can be carried in the pocket.

8124. But apart from practicability, I understand you to state that the use of the solution by injection has been a failure, whereas the use of the crystal is found sufficient?—We have not got many successful cases from the use of solutions, but I think that is largely due to their not having been used strong enough. I think that possibly a stronger solution might be effective, but it is much less practicable.

8125. An injection of Condy's Fluid?—Yes; it is certainly much more difficult to destroy the venom in that way. By rubbing in the crystals you get much more chemical action; by injecting subcutaneously it is liable to be absorbed.

8126. I take it that it must be a solution of the crystal in the blood or the lymph?—Yes, but it is a much more strong solution.

8127. But you do not attribute virtue to the dry crystals?—No, it has to be dissolved in the serum. I think that a very strong solution would be effective; but it is nothing like as practicable. It must act in solution, of course. I think it is purely a matter of dose.

8128. In a little paper which Sir Lauder Brunton handed in, which goes with Ferris and Company's First Aid Snake-bite Outfit, it is stated "The best remedy that can be carried for this purpose is permanganate of potash, the efficacy of which as an antidote to the poison, not only of the cobra, but of other venomous snakes, when properly applied, has been conclusively demonstrated." Do you think that statement is justified?—What is the date of that?

8129. It was handed in the other day?—Yes. The only two large classes, namely the cobra class and the viperine class, have two absolutely distinct actions. There are a few which do have a combined action to a certain extent, but the permanganate has been tested now against such a large number and found uniformly active, that I think we may take it as practically certain that it will act against any kind of snake poison. It has not been tested, of course, against every variety in the world yet.

8130. If that be so, in view of the heavy mortality in India, a heavy responsibility would rest upon the public authorities if they did not supply this apparatus?—You have to take into account the conditions in India. If you take, say, Eastern Bengal, where so many snake bites occur and where almost every house is separate, with a large number of rice fields between, there is practically no such thing as a village. When you come to hundreds of thousands of square miles of country like that, you can see how difficult it is to have the remedy always on the spot. But the Government are doing now a great deal towards distributing it, and I expect that we shall get good results.

8131. You say that the fact has been known for 30 years that this permanganate of potash is an antidote?—If mixed with cobra venom outside the body, it was known 30 years ago that it would destroy the venom.

8132. And presuming that the application was made in time, many thousands of lives might have been saved if what you tell us is correct?—It was purely a matter of getting a practical method of using it, which we now have but which we had not at that time.

8133. (*Mr. Ram.*) First with regard to viperine poison, you say that, if treated, it is counteracted by the use of adrenalin?—It counteracts the fall of pressure to some extent.

8134. In that particular case of treating viperine poison, experiments on animals would be shown to be doubly useful, would they not?—Yes, I think so.

8135. In the first place, you ascertain, I understand, by experiments on animals, exactly the mischief caused by viperine poison, namely, intravascular clotting or paralysis of the vaso-motor centre?—Yes.

8136. In the second place, having discovered the exact injury inflicted by the poison, you treat it with adrenalin?—Yes.

8137. Adrenalin also was discovered, was it not, in consequence of experiments on animals?—Undoubtedly.

8138. With regard to the snake bites, had they been investigated clinically for a great many years?—Yes.

8139. As I understand, as long ago as 30 years, by means of clinical research, the use of permanganate of potash was discovered as being advantageous?—Not by clinical work.

8140. Was it ascertained even as long ago as 30 years that the use of permanganate of potash was advantageous by experiments on animals?—It was discovered by experiments in order to try and find some antidote. They were mixing different chemicals with snake poison in order to see if they could find some antidote, and it was found in that way.

8141. Do you know what it was at the passing of the Act which hindered Sir Lauder Brunton from carrying on further experiments?—I do not know the details of it.

8142. You do not know what bit of the Act, so to speak, pinched him?—No, I have only his statement that that was the fact.

8143. I understand that horses, for instance, have been made immune by the injection of snake poison?—Yes.

8144. That was ascertained by experiments on animals, I suppose?—Yes.

8145. Solely and entirely?—Entirely.

8146. With regard to the use of permanganate of potash, you told Sir William Collins that it does not have to operate against mischief produced by an organism?—No, it has an antiseptic effect as well, which is useful; because there is a great tendency for septic changes to follow on snake bites, especially viperine ones. But that is not its essential action.

8147. But the mischief which it is intended to obviate and does obviate is caused not by an organism, but chemically?—Yes.

8148. Objection has been taken, as you no doubt are aware, by a good many witnesses to what they term the injection of any matter from any animal into a human creature?—Yes.

8149. This treatment of permanganate of potash on snake bite would not be open to that objection?—No.

8150. With regard to immunising horses by serum, is this the only case in which an antitoxin can be shown to be valuable against an evil which is not caused by an organism?—There are other chemicals, such as ricin and abrin, of which it has been said, that by injecting these into animals you can produce a serum which will even prevent the action of these chemicals, although they are of vegetable origin; but not against such substances as morphia.

8151. (*Dr. Gaskell.*) Those substances are also albumoses?—I think they are very closely allied.

8152. They are vegetable albumoses?—Yes.

8153. (*Mr. Ram.*) Then, except with regard to vegetable albumoses, the evil which the antitoxin can prevent in all other cases is produced by organisms. Is that so, so far as you know?—I believe so, so far as I know. I do not know the details of all those things.

8154. (*Sir Mackenzie Chalmers.*) Have you made any experiments with duboyi poison?—That is Russell's viper.

Major L. Rogers, M.D., F.R.C.P., I.M.S.

15 May 1907.

8155. What is that big snake that is so exceedingly poisonous?—The hamadryad.

8156. But there is another name for it?—The king cobra.

8157. Have you ever experimented on that?—Yes. I tested all these to see whether they had the same action as cobra venom, and whether Calmette's antivenin made from cobra venom would act against the other colubrine snakes, the hamadryad, the krait, and the banded krait. I found that they do have some action, but not enough to be of very practical use.

8158. The reason being that the physiological action of the two poisons is different?—No, the physiological action is the same. I tested them all first, and they all had the same physiological action in paralysing the respiratory centres—that is to say, all the colubrine class and the sea snakes. The cobra antivenin does have some effect against all those, but it is very much less than the effect against the cobra itself.

8159. And it has no effect when you get it against viperine poison?—It has no practical effect really against any but the cobra.

8160. But the permanganate of potash if applied instantaneously operates, so far as you know, on all snake poisons that you have tried?—Yes.

8161. Did not Dr. Douglas Cunningham try some experiments for the Government of India?—Yes.

8162. They were negative, were they not, in their results?—He tested a large number of reputed antidotes, but the results were all negative.

8163. And also he tried Calmette's and Fraser's antivenin?—Yes; he showed that it had an effect, but the effect was not very strong; it required to be much stronger.

8164. Was that on account of the small doses?—Yes; as a matter of fact, if you take a full quantity of cobra venom and you inject an average quantity, you will want 400 c.c. of Calmette's serum of the usual strength to neutralise it; that is why it is not very practicable; but, of course, a snake may often inject a small quantity, and then it may be efficient, but it cannot be relied upon by itself in every case.

8165. As regards the ligature, I suppose that the object of the ligature is to prevent the poison spreading into the system?—Yes.

8166. But if you could not apply the permanganate of potash for some time, do I rightly understand that in spite of any ligature the poison does get into the system?—I think that the poison would diffuse to a considerable extent in the limb, and make it much more difficult to neutralise it locally. When some time has elapsed I advocate making a much longer excision and applying the permanganate of potash more thoroughly.

8167. Can you catch up the poison then?—Not altogether.

8168. To some extent the permanganate gets into the circulation and catches it up?—The permanganate does not get into the circulation. I have tried that, and I find that you cannot do it, for this reason: If you use the potassium salt permanganate, it is too poisonous to inject in sufficiently large doses. I tried to use the sodium permanganate, but I found that upon sterilising it by boiling first a lot of it gets precipitated and it is very difficult to use—it is more unstable. I have not been successful with it.

8169. If you cannot apply the permanganate of potash at once and to some extent the symptoms have set in, I suppose you apply other remedies as well in addition to it?—Yes, certainly; you apply any remedy that you think may be of value in addition.

8170. How long after a bite is it of any use whatever to apply permanganate?—The longest case I have got was four hours.

8171. Does some part of the poison remain locally as long as that?—Yes, you can show it in this way: If you take a dose which is just fatal to an animal, if you inject it intravenously it will kill the animal in 20 minutes, but if you inject the same dose subcutaneously it takes 24 and often 48 hours to kill the animal; showing that it is absorbed comparatively slowly. I think the reason is the point which I have mentioned, that when you make an incision at the seat of injection you always find a bloodstained effusion of serum in 30 seconds. I think that is a protective agency to lessen the rapidity of absorption, as the absorption of a small dose is slow. So that if a very large dose is injected, a fatal dose may reach the circulation very rapidly before there has been much effusion to limit the absorption.

8172. Practically, then, the mortality of snake bite depends upon the amount of venom which happens to be injected?—Yes.

8173. And therefore all figures would be more or less fallacious, because it all depends upon the dose?—Undoubtedly.

8174. And to some extent, I suppose, it depends upon individual idiosyncrasy?—I doubt it. From experiments on animals I find no tendency of that kind. I should say that there is very little individual idiosyncrasy.

8175. It is almost impossible, I suppose, to get an intravenous injection by means of ordinary snake bite?—It might occur; in that case it would be fatal very rapidly.

8176. On the chance of its being intravenously injected, how soon would it be fatal—in a couple of hours?—If intravenously it would cause death quicker than that; it would not be likely to take more than 10 to 15 minutes, but even less.

8176A. In the ordinary case, when a fatal dose is not received, I suppose it is where clothing intervenes?—Yes, that is an important point. In this series I think that every one of the cases was inoculated not through clothes, but on the hand or foot.

8177. On the bare hand?—Yes, that is an important point in the series where the snake was identified.

8178. Because if a man was bitten through the trousers——?—He might probably escape altogether.

8179. Have you tried the effect of permanganate of potash on scorpion poisoning?—I have not done so myself, but it has been tried in Egypt, I am told, and it has been found to be equally effective. It is used now in Egypt, I am told, for scorpion poisoning.

8180. Rubbed in in the same way?—Yes, either rubbed in or injected.

8181. A great many natives in India are bitten by scorpions, are they not?—We do not hear much of it.

8182. Because the cases are not usually fatal?—Yes.

8183. Although they are very painful?—Yes, they are common enough. I have used the permanganate of potash in another way. I have found it very useful in preventing tetanus infection in wounds.

8184. Will you tell us anything that you know about that?—In Calcutta tetanus is an exceedingly common disease.

8185. Because the whole of the road dust is full of it?—Yes; so I carried out some experiments by putting a little dust from the Calcutta road under the skin of a rat, and I found that five out of six died of tetanus; but if I added a few crystals of permanganate of potash to the dust, then I only lost one animal, and that was not from tetanus. I then carried out a further series of experiments by scarifying the skin, rubbing in the dust, and using strong permanganate of potash solutions at different intervals, and I found by that measure also, even up to an hour afterwards, it was nearly always possible to prevent tetanus infection, although the control animals developed the disease. But permanganate of potash has also been used at my suggestion in cases of leopard bites. When persons are shooting in the wilds and there is no doctor near, permanganate crystals instilled into leopard bites, which are usually very fatal, in severe cases have prevented serious results from blood poisoning.

8186. The serious results arising simply from the dirtiness of the leopard's teeth?—Yes. I also suggested that it was worth trying in hydrophobia, and one of the medical officers in the South of India has used it in a number of cases of dogs which have been bitten by mad dogs, and a number of them have been saved apparently, and he is very enthusiastic about it.

8187. Using it according to your method of making an incision and rubbing in the actual crystal?—Yes, so that evidently of late it appears to be of very wide application.

8188. Is there a considerable death rate from tetanus at Calcutta at the present time?—Yes.

8189. And when a man scratches his hand on a road in Calcutta is this treatment applied?—They are

using the tetanus serum in Calcutta as a prophylactic. It is of very little use after symptoms have developed, but it is now used at the Medical College Hospital in all wounds that are thought to be likely to be infected with tetanus; and it has very materially reduced the number of cases of tetanus at the Medical College Hospital in the last few years.

8190. What is the incubation period of tetanus?—It varies very much, from seven to fourteen days. In the early days incubation it is much more fatal.

8191. In fact, the larger the dose the quicker the disease comes on?—Yes.

8192. When you have used the permanganate of potash have you also used the antitetanus serum?—In these cases in the Calcutta Hospital they only use the serum.

8193. They have not used the permanganate?—No.

8194. In your opinion, would it be desirable, say, first to use the permanganate?—Personally, I should do so.

8195. You would use the double treatment?—Yes.

8196. You would first try the permanganate?—Yes, and then get the serum as well, as a prophylactic. I have not had cases of my own to treat.

8197. I wanted just to get clear whether there had been any cases in which you used the permanganate of potash alone and where the treatment has been successful, other than experiments on animals?—Only in experiments on animals, so far as I know. I have not had any actual cases yet. I have not had any opportunity of using it myself, and I do not know how far it has been used.

8198. It would not be safe to use only the permanganate on man without trying the antitetanic serum as well?—I should use both where they were available; but the permanganate is much more likely to be available.

8199. Is there any danger from the antitetanic serum itself as apart from the disease?—I have never seen any.

8200. What symptoms does it produce?—A slight rash or edema, just as in diphtheria, but I have never seen any serious symptoms. It has even been used for injecting into the spinal cord recently in cases of tetanus, without any harm at any rate, and one case has recovered; but tetanus is a disease from which a great many cases recover, and you want a large series of cases to test it.

8201. Tetanus is not an absolutely fatal disease; there may be recovery with ordinary treatment?—Yes, especially under the chloral treatment.

8202. (*Dr. Gaskell.*) Do you know anything about the treatment for snake bites by swallowing the poison glands?—That was very carefully tested by Professor Cunningham. There was an idea in India that snake charmers produced immunity by swallowing snake venom; but Professor Cunningham fed a goat for, I think, two or three years on large quantities of venom, he gave some very large quantities, and in addition he gave all the remaining portions of any that he had used in his experiments, and he subsequently tested that goat with just enough to kill an ordinary goat, and it died in the ordinary time; so that I think we may take it as quite certain that it does not produce any immunity in that way. And that is what one would expect, because one would expect an albumose of that nature to be destroyed in the digestion and not absorbed as such.

8203. With respect to what you answered just now about antialbumoses, you know that if the serum of an animal is injected you can get an antiserum?—Yes.

8204. So that it is not only a question of albumoses?—No

8205. It applies to the various proteid bodies?—Yes, I was thinking at the time of the practical application.

8206. Do you think that snake charmers immunise themselves by small inoculations?—I think they do. I think that they often get little scratches, and get a little venom injected in that way. We had a man for many years at Calcutta who certainly had been scratched in that way repeatedly, and he was perfectly convinced himself that he had got immunity; and I know that Professor Cunningham thought so, too.

8207. (*Dr. Wilson.*) You said that in experimenting with this antivenin you found that it acted much more efficiently and rapidly if you injected it intravenously and not subcutaneously?—Yes, much more so.

8208. That, of course, would apply to the use of all sera?—I think so.

8209. In human beings as well as in animals?—Yes.

8210. So that to get the most efficient use of a serum, you would say from these experiments of yours, that instead of injecting it subcutaneously it ought always to be used intravenously?—Certainly in the case of snake poison where you want to get an immediate rapid effect, and, I think, also in many other cases possibly.

8211. But, of course, you admit that owing to the many difficulties which you have described, these sera, having to be manufactured for different snake poisons, until you get a polyvalent serum they are of little practical use?—That is my personal opinion.

8212. And I think you admitted also that in almost all cases which were brought to you, in the first series at all events, a ligature had been applied?—They were reported to me. I have not got full details of all, but I find there were four cases where a ligature was applied at once.

8213. And in the second series was a ligature also applied there; it would be, I suppose?—In regard to them I have not been able to get full details. I have corresponded with the people.

8214. I ask the question, because in China, according to a statement made by Mr. Cantlee, the well-known surgeon who has practised, as you know, out in China for a great many years, the Chinese immediately adopt the ligature; and he also says that it is a fact that very few Chinese die of snake bite. That is his positive statement?—I should like to know what the snakes are, and also how much venom they ordinarily emit, how many times what would be a fatal dose to man. You want to know all those factors. That is why I lay so much stress on our cobra cases, because I know that a cobra does eject on the average ten times a fatal dose.

8215. But, on the other hand, does it not appear that some considerable value might be attached to the use of the ligature?—I hoped so; but I may say that I did some experiments, but was not able to find it. It is a thing that wants further working out.

8216. Is it made part of the instructions which are issued with this lancet, that the ligature is to be applied immediately?—Yes. In my experiments with permanganate treatment ligatures were applied in nearly all the control animals which were injected with snake venom, but not treated with permanganate, but they all died in about the usual times, so that the ligatures alone completely failed to save any of them, even when only one fatal dose was injected.

8217. Now, with regard to permanganate of potash, are there other agencies, do you think, which would act equally well—for example, caustic potash?—Chloride of lime and gold chloride were found by Professor Cunningham to destroy snake venoms, but they are not nearly so practicable apparently as the permanganate; the gold chloride is exceedingly expensive while the chloride of lime is unstable.

8218. Have carbolic crystals been used?—I can not tell you absolutely. I know that Sir Joseph Fayrer and Sir Lauder Brunton tested a large number of things. I think that it was tested, but I cannot be quite certain.

8219. In early days, of course, permanganate of potash was a favourite antiseptic agent?—Yes.

8220. And in using it for tetanus, of course, in all the cases that go to you the wounds will be washed and cleaned, and so on?—Yes, but it is a curious thing with tetanus that ordinary antiseptics such as carbolic are certainly not as efficient as permanganate of potash. I remember a case of my own where the patient had been dragged along the road in London, and dirt had been grounded into the bone. I scraped it out most thoroughly, thinking of tetanus, and I used strong carbolic; but the patient developed tetanus, and Mr. Collier, the surgeon, informed me the other day that he had had similar results; so that permanganate of potash does appear to be specially efficient as an antiseptic against tetanus organisms, possibly. I think this is owing to its strong oxydising action against the tetanus bacillus, which is an

Major L. Rogers, M.D., F.R.C.P., I.M.S.

15 May 1907.

anærobic organism which cannot live in the presence of oxygen.

8221. But the serum now is only used as a prophylactic; it has failed as a cure?—It has not been successful as a cure so far as I know in my experience.

8222. (*Sir William Church.*) Now you are going to be good enough to give us some information on the subject of rinderpest. It appears that rinderpest had attracted the attention of the Indian Government for many years?—Yes, as far back as 1881, I think.

8223. And they have a bacteriological laboratory under their own supervision?—Yes, entirely for studying diseases of animals.

8224. Especially for studying rinderpest and other diseases of animals?—Yes.

8225. And in 1899 you were in charge of the laboratory?—Yes; it was in November, 1898, that I started, and I was in charge all through 1899.

8226. Would you tell the Commission what the work of your laboratory then was?—At that time I was appointed to act for Dr. Lindgard, who had gone on sick leave. Professor Koch had been working in South Africa, and he had also visited India shortly before. The whole question of inoculation against rinderpest was being worked at in South Africa, and the Government of India wished the methods there used to be tested, to see how far they were applicable to the conditions in India. There were two chief methods. One was the bile method of Professor Koch, which had done great service in the early part of the outbreak in South Africa, but which was at that time being discarded in favour of the serum method. The serum method was that of Turner and Kolle. It consisted in preparing an antidotal serum by injecting large quantities of virulent blood obtained from an animal suffering from rinderpest, because the organism had not been discovered, but the blood is known to contain the infection; and by repeated injections in this way into an animal which had recovered from rinderpest and so become immune, it was possible to produce in the blood of cattle a serum which had a very strong antidotal action against rinderpest. This serum could be used in two different ways; it could be used as a prophylactic injection by injecting the serum alone into an animal which was exposed to infection as in an outbreak. It was found that injection of serum alone would protect the animal for some weeks or months, and in Indian conditions would tide the animal usually over the particular outbreak in face of which it was injected. But that method of injecting serum alone only produces a temporary immunity of comparatively short duration. The second method of using the serum, the serum simultaneous method of Kolle and Turner, was to get permanent immunity for life by producing a slight attack of rinderpest in the animal injected; and this is done by injecting a small quantity of virulent blood containing the infection in one side of the animal, and at the same time injecting in a separate place a measured quantity of the anti-rinderpest serum, the strength of which has been previously ascertained. By this method it is possible to produce a mild attack of the disease in the animal, which will protect it for the rest of its life. This method was very successful in South Africa, but I found that it did not work very successfully in India. The reason for the difference was this. In South Africa the disease was a new one, so that all animals were equally susceptible, and consequently it was possible to regulate the dose of serum so accurately as to produce a mild attack of the disease in 90 per cent. of the animals, and yet not to have more than a half per cent. of fatal cases. In India, on the other hand, I found that owing to rinderpest having been present for very many years, the susceptibility of animals varied very greatly, so that it was impossible to so regulate the dose of serum as to get the results which were obtained in South Africa. If a large dose of serum was used so as to be sure of not getting many fatalities, then only a small number of animals, from 30 to 50 per cent., actually developed an attack of the disease, and so only that number obtained permanent immunity. If, on the other hand, the dose of serum was reduced so as to get a larger number of attacks, then the mortality was much higher than they got in South Africa. I found, however, that I could get over this difficulty, after long experiments, by using a large dose of serum to start with at the same time that the blood was injected, so as not to lose any animals, and then to any animals which did not react, which got no temperature or fever, or any signs of the disease at the end of one week, I found that I could then safely give a second dose of virulent blood, and then I nearly always got a reaction with permanent immunity; the reason being that those animals which did not react at the first inoculation were less susceptible than the others, and the serum was too strong to allow the virus to develop, but at the end of a week some of the strength of the serum had passed off, and then you could get the reaction safely. And this method I called the re-inoculation method. This method has been tested in the Philippine Islands, and is now being recommended in the Philippine Islands as preferable to all other methods of obtaining permanent immunity; but in India the method of simply injecting the serum alone is most generally used, because the more complicated re-inoculation method requires more skilful observers than are generally available. I may say that at the end of my year's work I made arrangements for turning out 100,000 doses of serum a year. I also inoculated a large number of animals myself in actual outbreaks. In two districts I inoculated over 500 animals that were actually in the same sheds with other infected animals, and at the same time I had notes of all the other animals similarly exposed to infection which were not inoculated because the villagers did not agree to it. These were all subsequently reinvestigated at the end of two months, and it was found that no one of the 500 animals which had been inoculated had developed rinderpest later than four days after the inoculation—that is to say, within the incubation period of the disease; so that those who developed the disease within four days must have been infected before the inoculation. We may say, therefore, that no animal which was not already infected subsequently developed the disease after inoculation in that outbreak. On the other hand, of about an equal number of animals similarly exposed to infection and not inoculated, one half developed the disease and half of those died, making a mortality of 25 per cent. of the uninoculated animals. These results were so conslusive that the Government of India arranged to turn out 100,000 doses of serum a year. Many thousands of inoculations have been done year by year since, and, I think it was last year, a second laboratory was sanctioned in the South of India because the one laboratory is not sufficient to make enough serum—the results have been so satisfactory.

8227. In what way do you deduce the variable susceptibility to the disease of cattle in India. What is the cause of the presence of rinderpest for so many years in the country?—Rinderpest is always present in India, and a very large number of districts are affected every year. You will find that one district will get rid of a lot of disease in one year, and after that there will be comparatively little for a few years and then you get another outbreak again; and when you come to an actual outbreak there will be a certain number of animals which perhaps have had the disease in a previous outbreak several years before, and those will be permanently immune

8228. Then an epidemic of rinderpest in India shows itself in the same locality during the life of the same animals?—It will not affect animals which have had it before, but there certainly is a very variable susceptibility.

8229. The interval between epidemics in localities in India is a short one?—Yes; it varies very much in different parts.

8230. But frequently it is short?—Yes. I may say that the natives are so fully aware of the protective action of an attack of rinderpest, that in the hill parts where the rinderpest is comparaively rare, and when it occurs it carries off 90 per cent. of the animals, an animal which has had rinderpest is worth double the value of one that has not. That is a very definite fact, and you can produce equal immunity by inoculation by the simultaneous or re-inoculation methods.

8231. That is your explanation of the varying susceptibility of Indian cattle?—Yes, that is so far as I can understand it. It is very difficult to explain, but it is a fact at any rate.

8232. Has the value of re-inoculation of cattle in India been recognised by the natives?—The re-inoculation is used very little in India, because, as I say, it is more difficult to carry out.

8233. But the value of your serum treatment has been recognised by the natives?—Undoubtedly. To give my own experience, after doing inoculations in three districts, the results of which I have just given you, I had applications from the natives to go back and do more in each place, although at first many of them had refused to have it done.

8234. From what class of natives would that be?—All the poorer village class; the ordinary agricultural labourer.

8235. (*Sir Mackenzie Chalmers.*) In what districts?—In Alleghur and Bulundhahar.

8236. In the north-west?—Yes.

8237. (*Sir William Church.*) Would they be Hindoos?—Mostly Hindoos, but a good many Mahomedans as well. I found when I got to a village that if the disease was still very prevalent and they were still losing animals, I had no difficulty in getting a good many done. I simply explained that it was just like vaccination, that as by vaccinating their children they were prevented from getting small-pox, so by vaccinating these animals we could prevent the animals getting rinderpest, and they understood it at once.

8238. So that these uninstructed and perfectly impartial natives were rapidly convinced of the value of it?—Yes; it touched their pockets, too, I may say. I found that some men who were selling cattle, when we wanted to have them inoculated said that they would not have it done because they wanted to sell their cattle, and they did not mind if the cattle got it after they were purchased; but when they belonged to the villagers themselves they were very keen about it.

8239. Do the animals suffer very much from which you get the blood—those in which you artificially produce rinderpest?—They certainly must suffer. The disease is more nearly like typhoid than any other human disease; you get ulceration of the intestines, and you get a high temperature, 104° or so, and the animals soon became drowsy rather like a typhoid patient; and when they get to that stage I do not think they suffer much, but they do get violent diarrhœa and running from the nose. They must suffer to some extent.

8240. Do you keep these animals until they die, or are they killed?—As soon as they have fully developed the disease they are bled to death. In that way you get your blood for injecting, and the animal is put out of pain.

8241. Have you any figures that you can bring forward to show the loss of life among animals during the last few years?—No, I have not. The disease varies very much. You get some epidemic years when they lose 100,000 animals in one district. In other years the disease is much more scattered.

8242. But if there is any value in this treatment, the epidemic ought to get less and less severe so far as mortality goes?—It is only the last six years that it has been introduced, and I have not been able to get at the Veterinary Reports. The figures have been published in Government Reports—probably I can get them at the India Office—showing the results of inoculations in the last few years.

8243. You think that figures will be available from the India Office?—I think I can get you figures as to the actual effect of inoculations in outbreaks.

8244. (*Sir Mackenzie Chalmers.*) It is only a very minute portion of the whole cattle in India that are treated?—There are several million cattle in a single district, so that you could not expect at present a marked effect on the whole of the cattle in India; but there are figures showing a very material reduction of mortality in particular localities; I think I can get you some.

8245. (*Sir William Collins.*) Is cattle plague distributed equally all over India?—Yes, I think pretty well all over India.

8246. Are there very large tracts of India which are free from it?—Not that I know. The hill tracts only suffer occasionally. The hill tracts may be free for several years at a time, but then you get very bad outbreaks afterwards. But in the plains it is practically always present, so far as I know, scattered about.

8247. What is the recognised administrative method of dealing with cattle plague in India?—It is practically impossible to do anything.

8248. Is slaughter of infected cattle carried out?—No, the natives will not allow it.

8249. Is there no attempt at the so-called stamping-out system?—It is quite impossible. You have to remember that the veterinary staff in India is exceedingly small. There is one veterinary officer for a whole province. They are being increased, but require to be increased more.

8250. (*Sir Mackenzie Chalmers.*) A province having from 30 to 70 millions now?—Yes, you have 50 millions in Bengal.

8251. There used to be 70 millions; now, since the partition, there are 50 millions?—Yes.

8252. (*Sir William Collins.*) Is the combined method of which you have spoken used now with Government sanction?—It is used where you can get the favourable conditions. It has been used in Assam among planters and people where it can be thoroughly carried out and where they understand it, but it is not used much by villagers; they prefer the simple serum method, because it tides them over their difficulties, and also because it does not make the animals ill. In several villages where the disease was not very prevalent I found that they would not allow the inoculation to be done. I had to tell them that by the serum simultaneous method the animals might be ill for two or three weeks, and they would not allow it. By the serum alone you get over the difficulty.

8253. Has the Government discouraged the use of infected blood because of the danger of communication of the disease to the animals?—No, I think not. Wherever it can be done it is done, but it is quite exceptional to find a place where the conditions are favourable in India.

8254. Do you think that there is a danger of propagating the infection by the use of this combined method, inasmuch as you are using the actual infected blood?—You only use it in an actual outbreak, where there is an enormous amount of infected cattle.

8255. But where there is an enormous amount also of uninfected cattle, I suppose?—But by this method the symptoms are very slight—nothing but a little fever; you do not get running from the nose and discharges which carry the infection, so that I very much doubt whether there is any material infection from animals with these very slight attacks as the result of inoculation.

8256. There have been previous attempts at vaccination against cattle plague, have there not?—Before South Africa?

8257-8. Yes. Have you heard of McPherson's experiments in Bengal a good many years ago?—Yes; he did some.

8259. He tried communicating the infection of cattle plague to the human subject, did he not?—I do not know.

8260. Have you heard of Furnell's experiments in Assam?—What date was that?

8261. I think it must have been in the thirties?—I do not know about that.

8262. Vaccination was tried against cattle plague, was it not—the use of cow-pox in this country in 1866?—I know nothing about the outbreak in England at that time.

8263. Are you able to institute a comparison between the so-called stamping-out method, if that were practicable, and the method of preventive inoculation?—Preventive inoculation I should say would be a thousandfold preferable to stamping out, as saving such an enormous number of animals which you otherwise would have to sacrifice.

8264. You spoke of a particular outbreak in which the inoculated animals did not suffer, or at any rate did not suffer anything like so severely as the uninoculated. Where was that?—In the United Provinces, in Alleghur and Bulundhahar.

8265. Has that been the subject of official report?—Yes, that is all in my Report to the Government.

8266. What is the date of the Report?—It was published in April, 1900.

8267. In what volume would that be?—It is a Special Report on Inoculation against Rinderpest—Report of the Laboratory.

8268. To the Indian Government?—Yes.

Major L. Rogers, M.D., F.R.C.P., I.M.S.

15 May 1907.

8269. Is it published in this country?—It is available in this country; it gives you the details and all my experimental results.

8270. (*Sir Mackenzie Chalmers.*) Of course as regards the stamping-out method by killing the cattle there is a religious objection in India?—Absolutely.

8271. It would be impossible in any Hindoo community?—Absolutely impossible; they would not consider it for a moment.

8272. So that, apart from the relative values, it would be an impossible thing for the Government to undertake?—Yes, absolutely impossible.

8273. There is one question that I omitted to ask you about snake poisons; I suppose it would be a very long time before the ordinary cultivator could ever be induced to carry about the permanganate of potash and the lancet?—Yes, the ordinary cultivator would not do it. The idea is to distribute it to the head men in the villages.

8274. In the first place, the ordinary cultivator has no clothes—no pocket, at any rate?—That is so.

8275. And no clothes in which he can carry it?—No.

8276. And it takes a long time to get an idea into his head about the treatment?—Yes, they tie up their pice in the corner of their dhoti; they might do it in time.

8277. (*Mr. Tomkinson.*) You are aware, of course, that there was a tremendous outbreak of rinderpest in this country some 40 years ago?—Yes.

8278. And no cure or preventive was known at that time?—No.

8279. They had to fall back upon the pole-axe altogether?—Yes.

8280. Is this discovery of yours protective only, not curative?—It is not curative. It has been used in that way, but it is not very efficient. I cannot tell you whether in the last few years they may have improved it.

8281. Then, so far, no cure has been discovered for an animal that is actually and virulently attacked?—I think not.

8282. Do I rightly understand that the instance about which you were asked by Sir Willian Church, as to the suffering of animals, was in the case of an animal being experimented on and inoculated with the virus of a dead animal?—No; I said that in preparing the serum, as there is no organism of the disease known, you have to take the blood of an animal that is suffering from the disease and inoculate it into the animal in which you produce the serum so that for that purpose you have to inoculate a certain number of animals with the disease.

8283. With the blood of the animal that has been attacked, naturally?—Yes; you have an animal which you inoculate with the disease in order to produce the disease, then you bleed that animal and use its blood to inoculate into the animal in which you produce the serum.

8284. From that second animal the serum is produced?—Yes, that animal is not killed.

8285. How much does that animal suffer?—That animal does not appear to suffer at all. You have to use an animal that has had an attack, or one which you have inoculated yourself; after that they get practically no reaction.

8286. Then they develop the serum which is required for a prophylactic?—Yes.

8287. Then in what way is that serum drawn from that animal's body?—It is drawn off from a vein in the neck, taking sufficient blood not to injure the animal, and then after a certain time you can take some more blood.

8288. Is it blood or a secretion?—It is the blood itself from which you separate the serum by a centrifugal machine, and then you add a little carbolic or lysol antiseptic and bottle it.

8289. Have you any idea how the disease originates otherwise than by infection or contagion?—It originates by contagion as a matter of fact. Unfortunately in India it is sometimes spread by the Chamars, the leather workers, who actually spread rinderpest in order to get the hides of dead cattle. It is a very difficult thing to stop.

8290. But any origin except that of infection or contagion has not been discovered?—No.

8291. (*Dr. Wilson.*) I suppose it is the horse that is used for rinderpest serum?—No; cattle are used. Horses are not susceptible to rinderpest.

8292. Would the serum, then, of an animal, which had an attack of the disease naturally, be looked upon as a prophylactic serum?—It would have some antidotal action, but not nearly strong enough to be of value; you would have to heighten it by further injections.

8293. Then the serum is used alone. You do not get the dual system?—No, we use chiefly, almost entirely, the serum alone in India.

8294. If a mild attack of the disease is induced by injecting the blood of a diseased animal it is merely a repetition of the old process of inoculation against small-pox; I mean inoculation from mild cases, as it were?—You cannot produce a mild case of rinderpest by inoculating from a mild case.

8295. It was believed in old days that you could produce small-pox in that way?—I do not think that is so with rinderpest. If you take a mild case it will produce a very violent case in an animal that is fully susceptible.

8296. By infusing the blood, you say, that a mild attack of the disease is induced, and, of course, that would produce immunity?—Permanent immunity is produced by injection of both virulent blood and the protective serum in a proper dose.

8297. But by the serum treatment it is temporary immunity?—It is temporary immunity which tides over that particular outbreak, but in a year's time the immunity will probably have vanished.

8298. So that you will have to go on?—If you get another outbreak you will have to inoculate other animals.

8299. (*Sir William Church.*) Could you tell the Commission anything about the working of the Kasauli Institute; do you know anything about it?—I know something about it. I have not worked there myself. Originally private subscriptions were raised in order to start a Pasteur Institute so that the treatment of hydrophobia could be carried out in India and the very serious delay of people going off to Paris could be avoided. When I went out to India first in 1893, subscriptions were being raised, and a year or so later one of the Anti-Vivisection Societies, I do not know which, sent out appeals to all the native Rajahs and people who had subscribed to this Pasteur Institute in India or had promised to subscribe to induce them to withdraw their subscriptions. However, Surgeon-General Harvey, at the Indian Medical Congress in 1894, gave an address on this question of anti-vivisection which neutralised that effort. Later on it was found that sufficient subscriptions could not be raised in that way, or, at least, before sufficient subscriptions were raised to do it in a private manner, the Government took it up, and I believe they gave a contribution equivalent to the amount which they had been spending on sending Europeans to Paris to be treated, and in that way the Kasauli Institute was started. The results are considered to have been so valuable that within the last year a second Pasteur Institute has been started in the south of India on account of the enormous area which has to be covered.

8300. (*Sir Mackenzie Chalmers.*) Do you know the results of the treatment at the Institute?—The figures are practically identical with those of Paris itself; the results have been very favourable.

8301. (*Sir William Church.*) Hydrophobia is not an uncommon disease in India, is it?—It is quite common.

8302. Has the population recognised the benefit of the Institution, or is there any difficulty in getting it recognised?—A large number of natives attend the Institute at the present time.

8303. Without pressure being placed upon them?—I think so.

8304. They recognise its value?—I believe so. I have not worked there myself.

8305. (*Sir Mackenzie Chalmers.*) Where can we get the exact figures?—I will look them up for you. I think I can find them for you.

8306. (*Sir William Collins.*) Is the Laboratory supported partly by Government aid and partly by volun-

tary contributions at the present time?—Yes, the original subscriptions were all funded. The Government pay most of the expenses, I think, now.

8307. (*Sir William Church.*) Is there anyone in this country at the present time who can give us information about it?—I do not know that there is anyone in the country who has worked there, but I shall be very pleased to look up the figures.

8308. I suppose the India Office would have them? Yes.

8309. (*Dr. Wilson.*) Is the Pasteur system of treatment carried out there?—Yes.

8310. But is not this new treatment, the permanganate of potash treatment, likely to supplant the Pasteur system?—We should not like to rely on it entirely by itself. I think it is a most useful thing to start with to save any loss of time.

Major L. Rogers, M.D., F.R.C.P., I.M.S.

8311. Is there a tendency to combine both systems?—In the south of India the permanganate system has been used more particularly in dogs in hydrophobia cases. How far it has been used in the human subject I do not know. It is only last year that these results were published. I do not think the system is very generally known yet.

15 May 1907.

Rev. John Page Hopps, called in; and Examined.

8312. (*Sir William Church.*) You appear as a witness on behalf of the Social Purity Alliance?—I think so; that is what I understand.

8313. You are a minister of religion in London?—Yes; Little Portland Street Chapel.

8314. Of what denomination?—Unitarian.

8315. You wish to give your opinion as to the ethical bearing of vivisection upon public safety and public morals?—Entirely that. I should like to say first that I am very glad to hear the question asked me just now whether I am prepared to speak on the ethical side of the matter connected with vivisection, because when I was asked to give evidence, I thought it would scarcely be admissible, and I thought I should almost have to apologise for consenting to be presented as a witness, seeing that I am not in any way an authority on the subject of vivisection, but I have been informed by those who asked me to attend, that this Commission is open to receive personal impressions and opinions as to the ethical bearings of vivisection upon public safety and public morals, and, if I may venture to say so, upon those who practice vivisection. Moreover, on the broad ground that the law should be mindful of morals, an advocate for applying the claims of ethics to vivisection, may perhaps justly have a *locus standi* here. As to matters of fact, I have therefore very little to say; mine are only inferences based upon facts, and I must not be personal. One possible justification for the presence of such a witness as I am may be found in an inference which very seriously bears upon what I have called 'public safety." The practice of vivisection, I suppose it is granted on all hands, undoubtedly produces a fascination for it which, in some cases, has confessedly risen to joy, and even to the perception of supposed religious sanctions.

8316. I would like to ask you at that point what evidence you can bring forward to support that statement?—I am proceeding to that. This may explain the dangerous suggestion made by one practitioner, that the hospitals ought to be supported, because "their inmates are made use of otherwise than for treatment"—a highly significant and sinister suggestion, which has very properly called forth from the other side the suggestion that the vivisector "is never safe to be trusted with a hospital patient on an operating table, and a tray of knives at his side." I do not say that is my opinion; I only say that I noticed both those statements.

8317. (*Sir John MacFadyean.*) Might we have references to the statements?—I should be very glad to supply them.

8318. Might we have them now. Who made the statements?—I have seen them stated. I will be very glad to supply the references later on. I am simply giving my own opinion in what I say. With regard to statements made by others I simply pledge my honour that I have seen them.

8319. (*Sir William Church.*) We do not for a moment doubt that you have seen them, but it is really quite necessary for us to know where you have seen them in order that we might see the nature of the context in which the statements have been made?—I think with regard to all other statements I do provide the authorities. An experimenter quite naturally desires subjects, and the temptation to seek them is great. There is a public peril here, because, unfortunately, in such a matter as this we must take the practitioners at their worst—in this case also the chain being no stronger anywhere than at its weakest part. Of course, it is well known that in Continental hospitals experimental vivisections of patients is common. The revelations of the "Deutsches Volksblatt" concerning the conducting of dangerous experiments purely for practice, and the inoculation with contagious diseases of young children and pregnant women, are not likely to be soon forgotten. One distinguished surgeon in Vienna frankly told the correspondent of the "Morning Leader" that in most free hospitals "patients are made use of in the cause of science," adding, "Tests must be made on somebody, and patients in charity hospitals are generally the only available subjects."

Rev. J. P. Hopps.

8320. I am afraid I must trouble you for the references. You have only given us the "Morning Leader." We wish to know who the Austrian surgeons are who have stated those views?—I am quoting from the "Star" of January 27th, 1899.

8321. We cannot accept the "Star" as an authority for what they state that people said in Austria?—Then I give it for what it is worth.

8322. (*Sir John MacFadyean.*) I submit another point. This evidence relates to Vienna—which is not germane to our inquiry?—I give it for what it is worth. I quote the "Star" of 27th January, 1899.

8323. (*Colonel Lockwood.*) It only refers to foreign hospitals?—We are all human beings, and what is human nature is human nature in Austria or in this country.

8324. (*Sir William Church.*) But you surely must realise that papers like the "Star" and many other papers are not very particular as to the truth of statements which they make. They will extract from a person's speech or writings a sentence which may bear a very different meaning from that which it bore in the original statement of the speaker or author?—I am very well aware of that.

8325. Therefore we must be referred, if you please, to the original published book or speech?—It was a statement made, according to the "Morning Leader" and the "Star" to an interviewer.

8326. It applies to foreign hospitals out of this country, where, of course, our law does not apply?—I only give it, as I think I said, as showing the natural effect upon a man who takes a very great interest in the subject—that is human nature; a man would like—I think I should myself, if I were a vivisector and thoroughly believed in it, and it was my profession—be very glad to get subjects in any direction, and if I was shut up in one direction I should try another and should pursue it to the very bitter end.

8327. (*Sir John MacFadyean.*) Might I ask whether there is any evidence that the medical man in Vienna who made these statements had ever practiced vivisection?—I know no more than I quote.

8328. Then it is not stated that he ever practiced vivisection. What bearing his inclinations might have upon the practice of vivisection does not appear?

8329. (*Sir William Church.*) We will not interrupt you, Sir, any more, but we will ask you perhaps after your statement has been made some further questions on it?—As to the ethical effects of vivisection upon the community, it is surely reasonable to suppose that the example set by such highly-placed men as adorn the medical profession will be followed by others, not so highly placed (I am speaking now of English practitioners) and perhaps not inspired by such beneficent intentions. The old jest, descriptive of the typical Englishman: "It is a fine day, let us go out and kill something," has its extremely serious side, and is connected with all the foul associations of what is called "sport." Of course it will be said that vivisection is justified because it has its uses in relation to the treatment of human beings. As to that I say nothing, except to remark that the medical profession is by no means unanimous as to it, and to add this doubt of my own—whether observations made during the special and artificially produced agony or distress of a dog

Rev. J. P. Hopps.

15 May 19 7.

on a dissecting table may not mislead when applied to a man in his bed. The expert ought to know best, but the common sense of it seems to be that every function and act of the organism would be affected, and, in some cases, violently affected, perhaps reversed, under torture. We know that secretions of every kind are so affected by fear, resentment, anger, shock or violent pain. What then would be the value of the observed action of drugs with a subject so affected? One can quite readily see that opinions arrived at in such circumstances might be dangerously wrong. Can any thoroughly reliable inferences be drawn concerning an acutely conscious man from the behaviour of a conscious, an unconscious, or a horribly tortured dog? Surely the torture is a *plus* which may mean a great deal. We know that anger can poison a mother's milk, and that a furious temper or filthy thoughts can produce vile tastes in the mouth, and play havoc with the heart, or, indeed, with every bodily function. Is it not highly probable that similar emotions *plus* agony may induce conditions and consequences which will go far to invalidate any conclusions that may be arrived at respecting the action of drugs? May it not be even dangerous to infer that what happens to an outraged—even if unconscious—dog will happen to a tenderly cared for child or man? But to return to my own province, the ethical consequences of vivisection, and may I venture to say, upon the practitioner himself. Here I really must apologise. I must take the preacher's privilege, for here nearly all is inference or moral probability. What, for instance, must be the ethical effect upon a man who revels in the disgusting work—who calls the ideal vivisector an "artist," and says, "The vivisector must approach a difficult vivisection with joyful excitement. He who shrinks from cutting into a living animal, or approaches an experiment as a disagreeable necessity, will never be an artist in vivisection!" The dreadful character of the vivisector's work will doubtless be described by others, and it may at all events be said of it that if a necessity, it is a painful necessity, and that the natural inference of it is the blunting of the fine moral sense. It may be said that this is the vivisector's business and that it is his own affair if he likes to take his chance. That is not so. The operator may be a physician, or a maker of physicians. He helps to create the atmosphere in which a powerful and beneficent, or possibly a formidable and maleficent, profession works. There is no need to be personal over this matter. There would be no end to that. It will suffice if we consider probabilities. What is likely to be the effect of practising vivisection upon men who so greatly need all the refinements of sympathy, if not its emotions? We seem to be living in a crisis of nervous maladies requiring not so much drugs as direction. The remedy for most of our maladies is not to be found in the carcase of a cat but in the soul of a man; and it is the more or less understood consciousness of this that has led to the great revival of "Confession" and the guidance of the priest in England. The question that trembles on the lips of thousands of sensitive spirits to-day is: "Can'st thou not minister to a mind diseased?" Whether the remedy sought will help or not in the end seems doubtful, but what is certain is that the Father Confessor, if he is to be of any use, must be skilled, not in the behaviour of muscles and glands and membranes, but in the subtle windings of passion, the treacheries of motive, and the dens or Elysian fields of love. The torture of a dog, the dabbling in blood, the abstraction of attention from agony, would spoil him "for the cure of souls"; and is not "the good physician's" vocation near enough to that of the true priest's to make some analogy, both of duty and fitness, useful here? Might it not even be said that the functions are often practically the same? If so, the paths of preparation for the one must be those of the other also. What tends to make the one gentle and keen, sensitive and pitiful, strong and wise, is needed by the other. But bloodshed blunts; and we are specially assured by zealous vivisectors that this is so, and ought to be so. How can it be otherwise? How could a man bear to carry through the tortures we have indicated, unless he acquired the necessary insensibility to, or forgetfulness of, the inflicted pain? And yet it is difficult to see how this could be acquired without deterioration. A man cannot win character and qualities all round, for all classes of work; and, though he may not be conscious of it, his creed is shaped by his actions, and not his actions by his creed. The great Dr. Abernethy's testimony has not been invalidated by time, "Vivisection has the direct effect of deteriorating the moral sense, and, once the moral sense is destroyed, it is impossible to foresee the consequences." I am willing to believe—I am anxious to believe—that in the great majority of cases vivisectors have honestly persuaded themselves that they are doing man service, and are suffering no harm in doing it. But it does not follow that the harm is not done because he who suffers it is unconscious of it. The unconsciousness may be a part of the harm, in the development of a certain narrowing callousness which may be almost like the closing of the Holy of Holies in the inner self. Can a man ever inflict pain, except for the actual sufferer's good, without deterioration of affection and pity? But affection and pity belong to the sphere in which a living man can alone become "a living soul." Knowledge and insight in that divine sphere are worth infinitely more than any knowledge and insight that can be gained in the vivisector's laboratory; and knowledge and insight gained there may be paid for at a fearful rate. The operator may be so absorbed in his study as to be, in a way, oblivious of the disgusting details, but that makes no difference, except as a grave suggestion as to what is happening to the operator. It has been very properly decided in this country that cruelty to animals is an indictable offence. Why? Surely because it is an offence against public decency and public morals to inflict torture. So much has this been felt that even in regard to criminals, we have steadily and of set purpose drifted away from torture as ethically bad. Cruelty, then, in any form, has upon it the brand of social and legal wrong-doing, and the burden of proof is heavy upon him who wishes to have it licensed by law. Suggestions as to the ethically bad effects of vivisection upon the operator are only inferences, but, of recent years, there have been sufficient facts to warrant them. Only last year, a professor—Professor Metchnikoff, at King's College, May, 1906—reported in the Journal of Preventive Medicine, August, 1906, lecturing at King's College, London, asserted that "in questions of health, morality should not attempt to lead hygiene, but should rather follow her," again a very sinister suggestion, which goes a long way towards justifying the statement that these questionable pursuits lead to questionable doctrines, if not questionable ethical practices, and, in the case of this professor, one is hardly surprised at finding him highly interested in syphilitic experiments with chimpanzees and baboons, with his eyes upon "the beginners in prostitution," and a commendation of the application to them—that is, the beginners in prostitution—of the chimpanzee and baboon experiments, as "an advantage to them as well as for the men having intercourse with them." I need not follow this up, in order to point the immoral moral of this odious suggestion. But, apart from this directly ethical view, there is the confessed selfishness of the whole thing, and with that I practically conclude; that enters into my subject of the ethical side of it. The justification of vivisection is based upon sheer selfishness. When all is said on the score of results, and the "artist in vivisection" has done his best to convince us that he is the apostle of mercy, many grave considerations "give us pause." For instance, what law of God or Nature justifies this treatment of our poor relations? Who gave to this amazing enthusiast the right to say offhand that he was at liberty to exploit the lower animals for experiments? What right has he to assume that these creatures are at his disposal for torture? If he proposed to kidnap or purchase cheap babies for laboratory purposes, his spectacles would not be safe in the streets; and if he put his proposal into effect, and got his babies on the dissecting table, the very costermongers would raid his laboratory, and even medical students might help them. Why? The cutting up of one baby might save the lives of thousands of other babies, and the torture of one for an hour might save thousands from suffering for years. But that would be no answer that society would accept. The killing of the cheapest baby would be murder, and its deliberate slaughter for any reason would be voted damnable. Why? Simply because of the egotism of the human animal, which has chosen to come to the conclusion that he is lord of all, with rights and sanctities inherent, which no other animal possesses. What ground is there for that? May not this conclusion of his be only the culmination of an insolent selfishness which, in action, may very easily make him the "inferior animal" after all? Not so far off, as some may imagine, this right to vivisect is related to the right of the odious vulgarian who desecrates the seashore and the beautiful cliffs for the purpose of shoot-

ing seagulls, whose bodies he is not over-anxious to possess; or that other vulgarian who thinks it sport to practice on pigeons, and other birds, preserved for the delectation of mere slaughterers. What right has this human animal to invade the right of his poor relations, and to rob them of their freedom and their life, for finery or for "sport"? Admitting that these are "inferior creatures," as well as "poor relations," what clause of any conceivable moral law hands them over to us for deliberate torture? Does not the whole thing turn, after all, upon the animal instincts which, at all the lower stages, suggest mere crass selfishness? But surely one of the notes of advance, one of the signs of civilisation, is the desire and the ability to win the higher and broader sympathies, and "let the ape and tiger die." And yet, after all, are we so absolutely sure that we know what birds and animals really are? Some of these not only astonish us with their faculties and affections, but entirely baffle and confound us before their mysterious performances. Is the carrier pigeon an inferior creature? Is the skylark inferior to the callous brute who would shoot it, or even eat it? Is the shepherd dog an inferior creature to the shepherd, who may get drunk every fortnight on bad whisky or raw rum? One need not be over fond of birds and "the lower animals" in order to be almost awed, at times, before their courage, their skill, their patience, their sensitiveness and good taste, their endurance and their love. There is a mystery here that we have not yet fathomed; and, before we talk so freely of "the lower animals," it might be well for us to consider whether we are in a position to judge as to what our relative places in Nature really are. Man's arrogance and masterfulness, always selfish and usually cruel, want repressing, not encouraging; and, in that repressing, we must be willing to pay the price, and to forego knowledge gained through the cowardly exploiting of weaker creatures. We must bid for the ideal man; and for this reason, that

> "When the Ideal Man shall reign
> In this world of tears and pain,
> God and man in him shall meet—
> Heaven his every sense will greet.
>
> He will be a vital part
> Of Great Nature's Mother-Heart.
> All that live, and all that feel,
> Will to his pure heart appeal.
>
> His great sympathy shall flow
> Through all forms of life below;
> Flowers and birds will talk to him;
> And the stars, like Seraphim,
> Through their Heaven-revealing eyes,
> Utter speech of Paradise.
>
> He shall be great Nature's heir,
> Lord of all things everywhere—
> Like a benediction dwell,
> Doing wisely all things well."

8330. Are you acquainted with the law of this country at the present time with regard to experimentation on animals?—I have read a very great deal about it on both sides.

8331. I beg your pardon, there cannot be two sides to the law?—I mean to say the law as interpreted by both sides, for there is a doubt, surely, about the interpretation of the law.

8332. I meant the rules and regulations laid down by the law with regard to experimentation on animals—the Act of Parliament—are you acquainted with that?—I think that, on the whole, I know it. I will not say that I am a legal expert, but I have naturally studied the subject.

8333. I only gathered from your statement that you were not acquainted with it, but I was mistaken, no doubt, in that. Would you tell the Commission can anyone perform these tortures upon animals?—No, I know that quite well. I am perfectly familiar with the fact that there are regulations, and that certain persons are authorised to perform them under certain conditions, but, surely, it is always an open question whether those conditions are complied with.

8334. Do you know what the conditions are that the law requires?—I cannot say that I could recite them; I know them in a general way.

8335. Would you tell me the general effect of them?—I should say in general, for instance, that, broadly speaking, the law requires that the animal to be experimented upon shall be made unconscious. That is what the law, I suppose, requires. I doubt whether it is done.

8336. Does it require anything further?—Will you ask me on any specific point?

8337. With regard to the unconsciousness of the animal?—I have said that the law requires, I suppose—I am not sure in all cases—but I suppose in general the law requires that the animal shall be made unconscious.

8338. What else does the law require?—From my reading of cases I should extremely doubt whether that requirement is always complied with.

8339. From your reading of cases you doubt whether that is complied with. I dare say you will be asked some questions upon it; but what further does the law require besides the animal being rendered unconscious at the time when it is operated upon. Were you not aware that it requires that the animal shall be killed before it recovers consciousness?—I am not aware that in all cases the law requires the animal to be killed: if so, I think that would rather strengthen some parts of my statement. I think it strengthens it in two ways: it strengthens it, in the first place, by the suggestion that the animal is terribly injured beyond hope of recovery; and it strengthens it in this direction, that the creature is entirely deprived of its existence. I do not say that that is a deplorable thing, but I only say that it enters into the case if the animal is rendered worthless and has to be destroyed, through being put under most terrible conditions of distress.

8340. But it is unconscious the whole time?—I doubt it.

8341. What are your reasons for doubting it?—I have read thousands and thousands of pages with regard to that, and I have come in general to that conclusion. I am not here to enter into that side of it. I am here to strongly speak on the ethical side, but I should have been prepared to enter largely into that side, for I have written upon it, and I have extreme doubts whether in very many cases the creature is rendered unconscious.

8342. You also say that the example set by highly-placed and conscientious men may be followed by men not so trustworthy and not inspired by such beneficent intentions. Do you know the terms of the law for obtaining these licences?—I know that the law is often evaded in all kinds of ways. We are living in the midst of law-breakers.

8343. Do you know how a licence for performing an experiment on an animal is obtained?—I do not know the details offhand.

8344. Were you aware at the time you wrote that statement that there is very elaborate machinery for guarding against a licence falling into improper hands?—I suppose it would be so.

8345. I ask you the question: Were you aware that there is existing a very elaborate set of regulations for preventing a licence falling into the hands of an improper person?—I have also a strong impression, from my reading, that it is made very much easier than your question suggests.

8346. Would you be kind enough to furnish us with what your reading has been which has given you that impression?—I shall be extremely glad to be privileged to attend this Commission again to do that. I propose to-day to speak only on the ethical side of the question.

8347. I think if you will merely furnish us with the names of the works which you have read, that will be sufficient. I suppose I should not be wrong in imagining that you would give us the pamphlets of the various anti-vivisection societies as being your authority?—With all submission, I think that you are going beyond your right in saying that. But I only profess to come here to speak on the ethical side of the question.

8348. You see, if I may say so, that we wish only to know on what grounds you are justified in coming here to represent the ethical side. You have not taken up the position that all experimentation upon animals and that all deprivation of animal life by man for any purposes whatever is immoral?—No, I do not take that line.

8349. Therefore we wish to know on what grounds you have formed the opinion which you have expressed?—I profess my statement, and I am perfectly

Rev. J. P. Hopps,

15 May 1907.

prepared to be examined upon the ethical argument which I have put forward.

8350. But in your *précis* you have made certain statements, and we are, I think, entitled to ask you on what grounds you have come to those conclusions?—I set forth all those grounds in my statement, the moral grounds and the ethical grounds.

8351. But you must have had some grounds; I want to know whether you were really acquainted with the law as it is settled, and you have answered that you do not know its details?—I only know in general that the law is as I state it—that it is understood that certain men have to prove so far as they can that they are right persons to perform such experiments.

8352. What is your ground for the statement that the medical profession is not united (of course, it is quite correct to say that it is not unanimous) as to the necessity for or the value of vivisection?—I think that has come within my own observation—that many medical men of standing do not believe it is of any use, but that it is misleading.

8353. That is another question?—That is the question.

8353A. Do you think that the bulk of the medical profession hold that view?—No; I should gather from my observation and reading that the majority of the medical profession believe in vivisection; but, as in the case of vaccination, opinion is divided.

8354. Then you laid great weight in the next statement that you made before us upon the point that observations made during artificially produced agony or distress may mislead?—Yes.

8355. Do you think that those persons who have studied physiology for many years do not know how to make allowances for those misleadings?—I can only say that I hope they do.

8356. They probably take that into consideration, do they not, in performing experiments?—To tell you the truth, I do not know what they take into consideration.

8357. But surely you would give them the credit for taking into consideration such very obvious things as that?—I do not know what the soldier in the heat of battle takes into consideration. He loves his profession, and he glories in the slaughter. Was it not Colonel Burnaby who was refused permission to go out with Kitchener to the Soudan, and in spite of the refusal he secretly went, and simply revelled in the fight?

8358. I do not think that comes into it?—I do not know. I think it is an answer.

8359. What do you mean by that; do you think that these experimenters revel in a number of experiments?—I should certainly revel in them myself if I were a vivisector. Every man loves his profession—loves the details of it.

8360. But there are not professional vivisectors, if I may say so. What do you mean by a professional vivisector?—I mean a man who regularly vivisects—a man who does it. I do not mean, and I do not believe, that it is a man's only business.

8361. What object do you think these people have in vivisection?—My dear Sir, I can imagine myself the delight there must be to the anatomist, for instance, in the dissection of the body. If I could do it, and loved it, I should delight in it for its own sake.

8362. I fail to follow you, but I will not ask you anything further on it?—It seems so obvious to me that a man who is a chemist must love his profession; it does not matter whether the man is making money or fame through it, the chemist must love his profession, and all the stinks of it. He must take delight in it. A great chemist in the north said to me, "People come here disgusted with the smell of this place; I love them all."

8363. Your own belief then is, that these vivisectors vivisect for their own amusement because they are so fond of doing it, and not for any purpose?—I would not say that. What I would say is that a man who believes in vivisection and believes that there are discoveries to be made which may be useful—I would admit all that honestly—thinks it is a useful thing, and may think he is doing God's service, even.

8364. Do you think people vivisect without a special object?—Yes, most assuredly; I should myself if I were a vivisector. I should experiment for the love of it.

8365. But you have no other ground except your own feeling for believing that?—I do not know; I think it is human nature. I think there are thousands of chemists to-day, and electricians, who are experimenting and worrying themselves, and working as hard as possible without any object except the chance of finding out something. I know it; I know many experimenters.

8366. And that is what you believe is the case with physiologists, too?—With many of them; I should think with most of them. I was going to say I hope with all of them. A man ought to love his profession.

8367. That is to say, that they put an animal under chloroform, and cut it up without knowing what they wish to observe?—No, I should not say that. The chemist knows what he wants to observe, the electrician knows what he wants to observe, but they do not know what is coming of their researches.

8368. Could progress ever take place in knowledge of any sort or kind if you knew beforehand what would come?—But then you do not know; the greatest discoverer does not know what is about to come. The man who discovered radium did not know what was coming. He was a seeker for years and years before he got the result, and the result came unexpectedly.

8369. You made a special reference, I think, to what you called Dr. Abernethy's verdict? What was that?—I quoted it.

8370. I am afraid I was unable to follow it; I was not acquainted with it myself?—Do you wish me to read it again?

8371. If you please?—"Vivisection has the direct effect of deteriorating the moral sense; and once the moral sense is destroyed it is impossible to foresee the consequences."

8372. Would you give me the reference to Mr. Abernethy—he was Mr. Abernethy. Was it in his lectures?—I will do my very best to find the reference. I have not got it here. I did not know that you required the book and the page.

8373. But you see you offer that as an important fact, and we want to know in what connection Mr. Abernethy said it. Do you know when Mr. Abernethy wrote that?—I was not with him when he wrote it.

8374. Do you know how long ago it was?—I shall be very glad to look it up and let you have the reference if you wish it.

8375. Did he write it before or after the time when anæsthetics were used in experimentation?—I cannot say.

8376. Then perhaps you would kindly let us know the reference?—I will do my best to find the reference.

8377. Do you consider that man has a right to use the lower animals for his convenience, and for his food?—For his convenience almost assuredly; for his food I have doubts.

8378. Are you a vegetarian?—No, I am not. I have very serious æsthetic doubts about it.

8379. But you are quite clear that man has no right to use the lower animals for the advancement of knowledge or the benefit of science, and indirectly, of medicine?—No, I have not said that. I think that man has no business to use the lower animals in the way of vivisection for that purpose.

8380. So that you would go for the total abolition of vivisection?—Certainly.

8381. Do you think that there is a great difference between seeing operations done on animals and seeing them done on man?—I do not know; I cannot say. I have never had any reason for observing. I have not seen them myself.

8382. But you are aware that in the medical profession, when men are learning their profession, they witness operations upon man?—I should think that in all these cases they are distinctly for doing good to the subject. That is not the case in vivisection.

8383. You stated also that you thought that there was a spirit arising which would lead to experimentation upon man in hospitals?—I should think that is very natural.

8384. But is not almost every case in hospital an experiment?—I do not think so; not for the purpose, surely, of finding out knowledge independent of the patient. I should hope that in every case whatever was done was for the patient's good.

8385. But is not almost every case watched in order that something perhaps may be learned from it?—That is very dangerous.

8386. (*Colonel Lockwood.*) You are entirely ethical, and you know nothing of your own knowledge as to experiments on living animals?—That is so.

8387. Or as to how they are conducted, whether under anæsthetics or without anæsthetics?—As to my own personal knowledge I certainly do not know. I should imagine that very few people are acquainted with that. One only gathers from one's earnest, honest reading.

8388. All your knowledge of experiments is second-hand?—It must be.

8389. And we are to take your evidence for what it is worth on the purely ethical question?—That is so; that is what I said.

8390. Can you suggest to this Commission any better regulations for experimentation on living animals?—No, I cannot.

8391. You probably would not like to suggest any, because you are against the practice altogether?—That is so. I cannot suggest any improvement of the regulations.

8392. That is all I wanted to know; you have no suggestions to make?—None whatever with regard to regulations. Simply on the ethical ground I am against the whole thing.

8393. (*Sir William Collins.*) You state in your *précis* that the practice of vivisection is ethically bad, and I understand you to say that it ought to be prohibited by law. Is that so?—I should think that it ought to be prohibited by law. I suppose it must be if it is to be prevented. What I should wish would be that men would not want to do it.

8394. But we are a Commission charged to advise His Majesty as to what alterations, if any, should be made in the existing law, and I wanted to know what suggestion you make in regard to that?—My position is that of an abolitionist.

8395. Is that because vivisection is ethically bad?—Not only on that ground; because I did venture in my statement to include a doubt as to its efficiency, its utility, and the possibility of its being misleading.

8396. If it were found to be useful and yet ethically bad, should you advise its prohibition by law?—I think I should, on the ground that I do not quite think we have a right to exploit these mysterious creatures, very mysterious creatures in my judgment.

8397. Is it because you think that everything that is ethically bad should be prohibited by law?—Oh, well, that is a very broad question. I want as little law as possible. I want men to want to do right.

8398. I can understand your being opposed to vivisection on ethical grounds yourself and your desire that other people should think with you; but I wanted to know whether you think that because it is ethically bad and perhaps useless as well, therefore it ought to be prohibited by law?—I think that vivisection should be prohibited by law. I should have to consider a good deal as to all kinds of ethically bad things. For instance, lying is ethically bad; I do not know whether you should prohibit it by law; it is such a big question.

8399. May I ask why you select this one of many ethically bad things for prohibition by law, while others would remain permissible?—That is a question which I have answered in my statement. It is ethically bad on various public grounds. For instance, take the case of a doctor. I have a reverence for the medical profession; I am not against doctors, I reverence them; every year I preach a sermon in favour of doctors, but I should be very sorry to have attending me, if I were ill, a doctor who was bluntly addicted to vivisection.

8400. I want to follow out how it would be practically possible, even if it were desirable, to prohibit vivisection by law?—I suppose you could make law that no one should practise vivisection, and yet many people would do it on the sly. I doubt whether you could actually do away with it by law, but I would like it abolished by law. I should doubt the efficiency of such a law, just as I doubt the efficiency of the law as it stands.

8401. Do you think that a more stringent prohibitive law than that which at present exists would be liable to be evaded?—I think so. I believe that the provisions of the law are evaded now.

8402. Then, is there any practicable suggestion which you think we could make to His Majesty as to the alterations in the law, if we desired to restrict vivisection further than the restriction which exists at the present time?—I do not know of any.

8403. Then, is it rather by propagating your views and educating opinion that you would attain your end, than by penal legislation?—I am afraid that the other method would take too long.

8404. What is the other method?—The other method is what you suggest, appealing to the law.

8405. That, I understand, you thought would be an impracticable method?—Yes, I do. I have said already that I do not suggest it.

8406. Then, there is no practical suggestion that you are able to make?—Except abolition.

8407. I understood you to say that that was not practicable, because it would be evaded?—There is always the chance that you may catch your criminal.

8408. I thought you admitted a large liability to his escaping?—I think that now, while you do permit it, you do get a certain number of people who practise vivisection under legal conditions, and they are not criminals and therefore they go on with it; but there are criminals—all laws are evaded; and I do not think it follows at all that you must not legislate, or that you should fear to legistlate, because the law may be evaded. The law now is justifying vivisection; I want the law not to justify vivisection

8409. Do you think that it raises public respect for the law if you pass laws which it is well known will be evaded?—I would like the sinner to be a criminal. I put it roughly, but you are putting it roughly.

8410. I have not yet got from you a valuable suggestion as to what modification, if any, is desirable in the law?—I have said over and over again that I do not propose any modification of the law. I want the law abolished.

8411. But you limit yourself to ethical grounds, and you do not wish to give evidence upon the scientific, or so-called scientific grounds?—I have said so. I am not a scientist.

8412. (*Sir John McFadyean.*) You desire to give evidence on the ethical side of the question, and I notice that you rather resent being asked any questions bearing on the actual practice of vivisection?—I do not resent it.

8413. But I am going to put a question to you in this way: Are not your views as to the morality of vivisection based on certain conceptions which you now have as to what the word actually covers in practice? I mean that vivisection calls up to your mind certain practices, does it not?—Yes.

8414. And it is on that that your views as to the morality of it are based?—Not upon actually what is going on.

8415. But surely your views as to the morality of vivisection must depend partly on what vivisection actually is?—What it is in itself.

8416. Then it is permissible for me to put to you a few questions to ascertain whether your views as to what vivisection as practised in this country really means are wrong?—No, that is not it.

8417. Perhaps the sentence was too long?—No, it is not that; it is vivisection *per se*.

8418. But there is no such thing, if you will allow me to say so, as vivisection *per se*. When you speak about vivisection before this Commission you must mean what is practised under that name in this country, must you not?—I do not know that that is so.

8419. Do you, or do you not, mean that?—No. I do not confine myself to what is vivisection as practised to-day. If there was no vivisection going on I should be opposed to vivisection *per se*.

8420. But vivisection is not an abstract thing. Your views as to the morality of it must depend upon what the nature of vivisection is?—Oh, no; you might just as well ask me about murder. I disapprove of murder *per se*. I am not to be asked whether I disapprove of murder as carried on in this country.

Rev. J. P. Hopps.
15 May 1907.

8421. Will you forgive me for saying that murder stands in no need of definition; but vivisection may. I will lead up to the point in this way. I notice that whenever you refer to the pain of vivisection you use expressions which indicate that in your opinion vivisectional operations in this country involve great pain. For instance, I noticed that you use the words "horribly tortured," "revelling in this disgusting work," "the artificially-produced agony in a dog," and other such expressions. I submit that it is perfectly fair for me to ask you what information within your own possession has led you to conclude that any experimenter in this country is in the habit of torturing a dog, or artificially producing agony in a dog?—If I had thought that I should have been asked for references to justify me in those statements, I should have brought my pile of books and publications, from which I could have quoted.

8422. I am afraid that you did not realise your responsibility. You have really made a very serious charge against licensed vivisectors in this country, and I submit that you ought not to have lightly done that without being ready to produce evidence of what would be an offence against the law, namely, for any licensed vivisector to artificially put a dog in agony, or to carry out any experiment which could correctly be described as "horribly torturing" that dog. I want to know, do you hold to these expressions as being correct?—Certainly; from my reading and conversations I feel justified in making the statements.

8423. Then I must ask you, for the information of the Commission, to extract from this huge mass of material some half dozen cases in which you think that the author's account of the experiments justifies their being described as "horrible torture"?—I have not restricted myself to the practice of vivisection in this country. I have written and spoken about vivisection as practised anywhere.

8424. I will put it in this way: This Commission has only got to deal with vivisection as practised within the limits of the three kingdoms. Supposing the Commission, from the evidence put before them, arrive at the conclusion that your estimate as to what vivisection is is totally wrong, that is to say, that it does not involve the horrible torturing of animals, would you admit that the Commission ought to discount your evidence as to the morality of vivisection?—I do not think so.

8425. I am quite satisfied with the answer. Did I rightly understand you to mean that man is never justified in inflicting pain upon an animal, except for that individual animal's good?—I did not say that.

8426. Will you tell me what does justify man in inflicting pain upon an animal?—If I answered broadly Yes to that question, you might say that a man must not give his horse a taste of the whip. It is a big broad question. You may do all sorts of things. You may whip a dog that you love passionately?—I do not love any dog at all, but I have seen women who do give a dog a lash with the whip.

8427. Are these words not to be found in the evidence which you read to us a few minutes ago?—I do not think so.

8428. I submit that the words "Causing pain except for the animal's good" came in in some connection, and I wondered in what connection it was. You objected to vivisectional experiments because the pain was not inflicted for the animal's good, did you not?—Yes. But taking vivisection as it, there is a difference between vivisection and a lash of a whip.

8429. Taking vivisection as you conceive it to be, if you will forgive me, I think is a safer expression?—As it is in the world at large.

8430. You do admit that man is justified in certain circumstances in inflicting pain on the lower animals?—It is a broad question to which I could not say yes or no.

8431. I will also take that for an answer?—I would like to get at the bottom of it, and I think in five minutes we might if we talked it out. It is such a broad question. It is a question which seems to seek for an admission which will be turned to my disadvantage.

8432. There is no question of disadvantage really. We are seeking here to arrive at the truth?—It is a criticism of what I said in my statement, and you are putting a question as broad as that—"inflicting pain on animals." There are grades of pain from the lash of a tiny whip to cutting up an animal alive.

8433. I will help you out with it. Is man justified in inflicting on the lower animals considerable pain for any other purpose than the individual animal's own benefit?—Any vivisectional pain?

8434. Let us put aside the way in which it is inflicted. Is man in any circumstances other than the individual animal's benefit justified in causing considerable pain?—There must be degrees when you speak of inflicting pain. I will give you a case. I do not love my dog; my wife does. I have seen her give it three strokes with a whip—gentle strokes, fairly gentle—and I have thought: Well, on the whole, it is rather a sharp thing to do. But if she were to kick that dog mercilessly, I should say it was base. It is a question of degree.

8435. I will put the question to you in this way: Do you think that man is justified, for the mere purpose of improving the quality of his animal food, in subjecting male animals to the severe vivisectional operation which is known as castration. You know what the operation of castration is as applied to an animal?—Yes, but is that for the animal's good?

8436. Although you have never seen it done, with the imagination that you possess you must be able to figure to yourself how exceedingly painful an operation it is when done without anæsthetics. Do you think it is justifiable?—Did you say for the animal's good?

8437. I did not say that?—I thought you did.

8438. I said that it was done for man's good—to improve the quality of his food?—I should not like the man who did it.

8439. It is not a question of the man who did it. Will you answer the question?—But there might be hundreds of questions of that kind, and I should give that sort of answer to them all.

8440. But I do not know what the answer is. Do you think it is justifiable?—No.

8441. I want to see whether you are perfectly consistent. Do you invariably ask for bull beef when you send to the butchers' for beef?—Never. I did not know that there was any difference.

8442. You will find the difference if you ask for it once and get it. Do you not think that it is very inconsistent in you, merely for good digestion or taste?—But I do not.

8443. But you spoke elsewhere of foregoing advantages derived from vivisection; why should you not set your face against this cruelty?—I should, decidedly. If a butcher told me, Here is one bit of meat got through this operation, and here is another, I should say, I will have neither of them.

8444. That is hardly going far enough. Ought you not to ask for bull beef, for instance?—I did not know there was such a distinction. I am not such a connoisseur, such a *gourmand*, in the matter.

8445. That is because you have always eaten the good sort, which is got by a painful method?—No, because I shrink from eating meat at all. I take no interest in the matter. I am almost persuaded to be a Christian in regard to that.

8446. But you are not quite consistent?—I admit it; I am not.

8447. (*Mr. Ram.*) Do you deny that any useful knowledge has been, or can be, obtained by vivisection, or that in any case would the acquisition of such knowledge be lawful?—I do not deny that knowledge can be obtained.

8448. Do you, then, deny that in any case it is lawful to attempt to get such useful knowledge?—Through vivisection it is not lawful.

8449. Do you base your objection to vivisection wholly upon the pain inflicted upon the animal?—I have never seen vivisection done, but I should imagine that there are various sorts of distress, not merely pain; but distress would be pain, too. I do not know what happens to an animal under vivisection, except that there are all the signs of misery, apparently.

8450. All the signs of misery, apparently?—Yes.

8451. How do you know that?—In all the experiments I have heard of—not on one side, as was suggested just now, from anti-vivisection societies, but I have read books and pamphlets by believers in vivisection, which indicate distress.

8452. Accounts which indicate distress?—Distress and agony.

8453. Then may I take it that it is because of the pain in the cases of which you have read that you base your objection to vivisection?—Not entirely; that is one reason.

8454. You have told me that useful knowledge may be obtained?—No.

8455. I asked you whether you deny that knowledge may be obtained, and you said no?—If there were. I do not say that there is.

8456. Take it hypothetically. If useful knowledge can be obtained by vivisection of an animal which is subjected to no sort of pain or distress should you object to that vivisection?—I do not know that it could be.

8457. But you see you have come here to talk ethically to us, and I am trying to get really at what is your meaning?—Is it possible that you are in earnest?

8458. We have heard of many cases of it; anyhow, will you kindly imagine an animal subjected to no sort of pain or distress at all, an animal put under anæsthetics without pain, which is to die before it recovers from the anæsthetic. Is it wrong in such a case to attempt to get knowledge?—I do not know what happens under anæsthetics; I cannot say. There are degrees of the distress.

8459. I am putting to you the case of an animal that is absolutely anæsthetised, and without pain or anæstheic before it can possibly recover any consciousness. Is it wrong to attempt to obtain useful knowledge by examination of that animal?—I do not know that it is quite fair to put a hypothetical case like that.

8460. I will take that answer, if you please. May I take it that you decline to answer that hypothetical case—is that your answer? (*After a pause.*) Is that the answer?—It would be a hypothetical answer to a hypothetical question.

8461. Let us have the hypothetical answer if you cannot give anything else. What is the hypothetical answer?—That is the answer.

8462. I will leave it there if you like. Do you think it is wrong for a surgeon to gain knowledge of anatomy through examining a dead animal?—No.

8463. Do you think it is wrong for a surgeon to kill an animal painlessly in order that he may examine it after it is dead?—I think it is.

8464. Is it wrong under any circumstances to take the life of an animal?—I do not think it is. That is my present stage. I have a doubtful opinion about it. I have said that already. With regard to killing animals for food, I am in a transition stage, as many men are.

8465. Since luncheon?—No.

8466. Was it permissible to kill the animal of which you last ate a portion?—I am in doubt about it.

8467. Take the case of the Dogs' Home. There is a miserable, lost, suffering, diseased dog at the Dogs' Home; no one claims it; it is put into the lethal chamber, and perfectly painlessly it dies. Is that right or wrong?—That is all right.

8468. Are you sure of that?—Yes.

8469. Thirty thousand dogs a year?—If you give me the case of an individual dog I will give you an answer. Your question a little while ago was so broadly hypothetical that it covered my wife's dog.

8470. There was nothing broadly hypothetical about the case of the animal that was killed to give you the last meal that you had of animal food. Was that right or wrong?—That is too broad.

8471. I come to the individual animal, the last animal that was killed in order that you might have animal food. Was that right or wrong?—I say I am in doubt about it; I am in a transition stage, as a vast number of men and women are to-day about that.

8472. You have not made up your mind what you will have for dinner to-night, then, I take it?—Very likely. Over and over again I say, "No, thank you, no meat."

8473. But still you are weak enough to take some?—I am in a doubtful frame of mind about it.

8474. Would it be the same thing with regard to fish and soup?—Yes.

8475. You are a vegetarian pure and simple?—No.

8476. Is it wrong to kill animals painlessly in order that their hides may be turned into leather?—That, again, is a doubtful question.

8477. I think I see a pair of very well soled shoes?—I know; I know we are all inconsistent.

8478. I am glad to say I am not in the least inconsistent about that?—We are all inconsistent—we are bound to be. You see some things clearly and other things you see doubtfully.

8479. You put the case of vivisecting a baby, and you said that everybody would rise with horror against such an idea. Do you put babies and animals exactly on the same plane with regard to vivisection?—That is precisely what I did not do. I drew a broad contrast.

8480. What is the contrast?—That is what I want to know. That is the question I put in my statement. That is a question for the vivisectors to answer.

8481. I thought it was rather a question for an ethical professor to answer?—No. It is a question that I have put to them.

8482. There is no objection to eating an animal that has been killed for food, at all events, if you have no doubts about it, is there?—But are there doubts?

8483. There is nothing wrong in eating animals as food?—That is the same question. I am in a doubtful state of mind about it.

8484. Is it doubtful whether you ought to eat a baby killed for food?—No, it is not.

8485. What makes the difference between a baby and a sheep?—That is what I want to know. I have been asking that. My statement asks that.

8486. We think that we do know?—No. I want an answer from the vivisector. The vivisector is bound to answer me that.

8487. Do you think it is wrong to drive a horse in a cab?—No.

8488. Do you think it is wrong to drive a man in a cab?—If the man liked it——.

8489. But if he did not like it, with the assistance of the whip, is that right or wrong?—I should think it very wrong.

8490. Why is it right to drive a horse and not right to drive a man?—Well, you can consult the man; you cannot consult the horse.

8491. But supposing the man says "No," and yet you drive him, is that right or wrong. Wrong you would say?—No, I would not.

8492. Not wrong to drive a man if he said "No"?—I should ask whether you are in earnest.

8493. Whether I am?—Yes.

8494. I am absolutely in earnest. I want to get at the distinction which you have quite gravely put to us, and I am quite gravely wanting to ascertain, if I can, the meaning of such phrases as you have used here. Why is it wrong to drive a man against his will and not wrong to drive a horse?—So far as I can get into the mind of a horse the horse has no opinion upon it; the man has.

8495. Is that the reason why you think it is right to drive a horse and wrong to drive a man—because the horse does not care whether it is driven or not?—No, it is not that. I do not know what the horse thinks about it; I have no means of knowing the horse's mind. I know the man's mind. But it may not be wrong to drive a man in a cab if he is foolish enough or slavish enough to permit it.

8496. Is that the only answer which you desire to give?—That is the answer.

8497. That is in your mind the distinction between so treating a man and so treating a horse?—Yes, that is the distinction.

8498. Can you give any other distinction?—That will do; that is enough.

8499. And you cannot give me any other?—I do not think that any other is needed.

8500. Have you any other that you could give me. (*After a pause.*) May I take it that you have not?—You may take it that I think that is the necessary answer; that answer is all that I care to give.

8501. I have only a little more to trouble you with.

Rev. J. P. Hopps. 15 May 1907.

Will you tell me this: have you any suggestion to make as to the recommendation which this Commission ought to make to His Majesty the King?—I have already said that I should be delighted if the Commission would recommend that vivisection should be abolished by law, that is to say, if vivisection were not recognised by law.

8502. Then that means that you desire the repeal of the present Act?—Certainly.

8503. And would you desire the enactment of any Act, and, if so, what, in its place?—It is immaterial whether you abolish the present Act or pass an Act forbidding vivisection. I should prefer that an Act should be passed forbidding it.

8504. Abolish the present Act and pass an Act forbidding it?—Yes.

8505. Do you think that would stop vivisection?—I am afraid not.

8506. Which do you think is the worse, so far as vivisection is concerned, the state of affairs in England or the state of affairs in either France or America?—That I cannot say.

8507. You have not studied it?—I have generally read about it, but I do not know truly what is going on in England.

8508. Do you know what is going on in either France or America?—I have read of it.

8509. Have you read of the horrors which take place there?—I have read very much about France.

8510. Take France, then. Have you read about the horrors that are taking place there?—Yes.

8511. Are you aware that there is no law regulating vivisection in France?—I have already said that I should like a law passed forbidding it.

8512. But are you aware that to-day there is no law in France which regulates vivisection; do you know that?—I took that for granted from what I have read.

8513. You know that there is a law in England which regulates vivisection?—Yes.

8514. Which do you think is the better condition with regard to vivisection, the state of things in France or the state of things in England?—That is not a fair question, because I have already said that I want a law passed to forbid vivisection—to make vivisection criminal.

8515. If you do not like to answer the question I will leave it. You want to make vivisection criminal?—Yes.

8516. Would that be wholly regardless of the object with which any vivisection might be performed—that you would make it criminal in every case?—Yes.

8517. Would you also make criminal the performance of any operation on any animal except for that animal's good?—Speaking generally I should.

8518. Are you aware of the farmyard operations which take place by the thousands every day on colts and young stock of all sorts?—For the animal's good?

8519. Not in the least for the animal's good: in order to make their meat taste better for man. Would you allow them or disallow them?—I should disallow them.

8520. Would you make them criminal?—Is there vivisection?

8521. Undoubtedly there is vivisection of a most exceedingly painful kind without any anæsthetic?—I think I should.

8522. You would make it criminal to perform any such experiments?—I think I should.

8523. You said that the practice of vivisection was ethically bad and hurtful to public morals, because it is based entirely upon human selfishness and the assumed right to capture, torment and destroy animals for repeated experiments that may prove nothing, or mislead, and for experiments which turn upon distress, and begin and end there. Is it because those experiments, as you express it, in your opinion, are for torment, and turn upon distress, and begin and end there, that you object to them?—That is the general reasons—that is the ethical reason.

8524. And if experiments did not torment, and did not turn upon any distress, or inflict any distress at all, should you still object to them?—I do not believe it is possible.

8525. Will you imagine the case?—I cannot imagine it. I do not trust my fellow creatures enough.

8526. To do what—to imagine a case?—To keep within the limits of what you suggest. You see what I mean.

8527. No, I do not in the least.—There is the old hypothetical question again. The answer must be hypothetical. If human beings could be trusted to keep within those limits, I might say that I did not object. I think it is too dangerous.

8528. Is it because you do not trust any of your human fellow creatures?—I do not say "any."

8529. Because you do not trust some of your human fellow creatures to abstain from unnecessary pain, that you would object to vivisection altogether: is that the reason?—It is very near it.

8530. Can you put me any nearer, or do you adopt those words?—That is quite enough.

8531 (*Mr. Tomkinson.*) By the repeal of the law you mean, I presume, that the immunity which is given to the system now should be removed, and that all experimenters should be subjected to prosecution for cruelty to animals?—Yes.

8532. That would be the effect of a mere repeal of the present regulations?—I think that is so.

8533. Would you go further and have a special Act passed to make vivisection criminal?—If the mere repeal would be sufficient I would not want a law to specially make it criminal.

8534. You have been asked as to whether you think the results of a repeal of the law might be ill. Of course your object is to diminish the sum of animal suffering?—That is the main object, but it is not only that. My statement indicated other reasons—to diminish the danger to the vivisectors, for instance.

8535. It has been put to you whether the result of abolition might not be to drive more of the system into other countries, where infinitely less mercy is shown to these animals?—That is likely.

8536. Or whether, secondly, it might drive the practice into secrecy?—That is very likely.

8537. Instead of its being practised openly in laboratories?—Is it?

8538. Not openly to the public—I mean that there is inspection—that it is under regulation; that it might have a tendency to drive it under the surface and into secrecy in private houses?—Yes.

8539. That occurs to you as a possible alternative?—Yes; but that is true of a great many things, you know; that is true of prostitution. Those questions all require a good deal of discrimination in both asking and answering. You may drive a thing under the surface and make it worse—one admits that possibility; but none the less should the State, the nation, clear itself.

8540. Of complicity?—Yes, that is what I should say.

8541. In regard to the question of exploiting animals for food, I gather that your mind is in a state of suspension?—In a great state of suspense.

8542. You said something in your statement about sport, but you only instanced such a thing as pigeon-shooting?—Yes.

8543. Does the same objection apply to all sport?—It applies to rabbit coursing and all those things. I would not apply it to horse racing, for instance.

8544. But to shooting?—Yes, I should think so. I never read, for instance, about the King's kind of shooting without a feeling of disgust.

8545. If you object to shooting, would that lead you logically to refuse to eat a pheasant or a partridge?—It makes me feel on the whole that I rather want to be a vegetarian.

8546. I see that you are turning that way; but hitherto you have not refused to eat a pheasant or a partridge?—I have eaten them.

8547. But you must be aware, as we all are, that an immense amount of cruelty is committed in even slaughter-houses?—Yes.

8548. And that pain is inflicted upon animals in those various operations which have been spoken of?—Yes.

8549. Do you draw any distinction with regard to

animals. You admit, I suppose, that it is necessary to destroy rats and animals of that sort?—Yes.

8550. Otherwise it would be a case of being eaten up by rats?—There again it is a question of degree—how you destroy your rats. There is a certain way of destroying a rat which is permissible. There is another way of destroying a rat which is vulgar and brutal.

8551. In regard to the common way of destroying or diminishing the number of rabbits, have you thought what trapping means? Have you ever seen a steel trap, which is the common mode of catching a rabbit?—No, I have not. I can quite imagine that very many ways of destroying wild animals are very brutal.

8552. They are extremely cruel. Do not you think that, logically, one ought to set one's face against that, as well as against vivisection?—I should be very sorry to catch these creatures in that cruel way.

8553. Then, as to that distinction of stray dogs, this instance has been put to the Commission: given a dog that is under sentence of euthanasia, to be put into the lethal chamber——?—I rather like that.

8554. Would you protest against that same dog, which is under sentence of death, being utilised for some experiment?—I should not feel enough faith in my fellow-creatures to believe that it would be used without what I disapprove of. The lethal chamber, I suppose, is a genuine article, and there is no distress there, and there is no risk of margin for prolonged agony. In fact, I would rather like to be put in the lethal chamber myself if I were under sentence.

8555. With regard to that question which you found it so difficult to answer, I imagine that it really amounts to this: that you are sceptical as to perfect painlessness being insured, or anything approaching to perfect painlessness?—That is a very essential part of my feeling.

8556. But, even if you could be satisfied that no pain was inflicted, you would still object to the principle?—Not only to the principle; but, in my short statement I give two or three reasons why I think, apart from the misery of the animal, it should not be allowed—namely, the doubt as to the results being of value or the reverse, and the doubt as to the influence on the vivisector's ethical condition. That is a very important matter.

8557. You are aware, probably, that an enormous preponderance of operations on animals are very slight operations, of inoculation?—Yes.

8558. Operations which, in themselves, practically cause no pain?—Yes.

8559. To those you have less objection probably?—Certainly.

8560. (*Sir Mackenzie Chalmers.*) You have given evidence on the ethical side of vivisection?—Almost entirely.

8561. You know that other people take a different view from that which you take?—Certainly.

8562. And that, although, ethically, to you it is wrong, it is justifiable to other people?—That is all we can do.

8563. I want to ask you what is your test of what is ethically right or wrong—your own particular conscience?—My own conscience, my education, and my general spiritual condition.

8564. That is to say, it is merely a question of individual judgment?—Certainly.

8565. You have no outside standard to apply?—No. In regard to matters of this kind one must judge from one's own spiritual and moral condition as to what is right for others, although they may not feel it so. You must go by your own judgment and moral sense in any case.

8566. And where there is a conflict of what I may call ethics, or ethical opinion, is there not great difficulty in legislating?—You do not find it so in ordinary life. Lying is lying.

8567. But you would hardly legislate against lying?—I would not legislate against lying.

8568. You would not?—When it came to practical operation, as in lying about a bargain, or fraud in relation to a contract, you must legislate; but against lying as lying you cannot legislate.

8569. Are we talking always of the same thing. What do you understand by vivsection—any experiment on animals, or only experiments producing pain?—I have freely said that there are grades of objection to vivisection; it extends from kicking a dog, which I mentioned just now, up to most cruel experiments. There are various grades of objection.

Rev. J. P. Hopps. 15 May 1907.

8570. By vivisection, you mean anything that would cause pain to an animal?—That is rather too broad a definition. If you added "for the animal's good" the objection does not quite go so far.

8571. Are we talking about the same thing when you object to vivisection, and other people are in favour of it, or are we covering different spheres?—I do not know at all. I should have to get into your mind.

8572. That is why I asked you how you would define vivisection?—I cannot define it except by taking the dictionary meaning of the word: "Cutting up an animal alive." Then I say that there are endless grades of objection from what is almost unimportant up to devilry. And then when you ask: "Are we talking about the same thing?" I should say that we are talking in the main about the same thing; but perhaps we may not at the same moment be talking about the same degree.

8573. Do you object, for instance, to feeding experiments. A great many experiments which are licensed under the Act are feeding experiments?—I do not know much about them. I know nothing about them, in fact.

8574. They come in under the present law, as you know?—Not under vivisection.

8575. They have to be licensed?—That is another thing altogether; but I know nothing about them at all.

8576. But still they are included in the returns of experiments?—They are very improperly called vivisection.

8577. As you are aware, there is no such term as vivisection known to the law. The existing law of England deals with experiments upon animals?—Yes.

8578. Have you ever read the Act?—I must have read it.

8579. You will find that the word vivisection is not mentioned; it is a law regulating experiments on animals. What I want to know is how far you object to all experiments on animals?—I know nothing whatever about the feeding experiments regulated by law. I did not know that they existed. I knew that there were very many experiments as to foods, that is to say, with human beings.

8580. Still if by any proposed amendment of the law you took the existing Act and made all the experiments under it unlawful, you would make feeding experiments unlawful. You would not wish to go so far as that?—I should like to know what those feeding experiments were; they might be abominably cruel. You might stuff an animal till it was suffering greatly.

8581. I will give you an example. A licensed experimenter applied the other day for leave to feed kittens with cow's milk instead of cat's milk, to test the effect of changing the mother's milk. Would you prohibit that?—Well, putting it as you do, I should say that I would like the Act entirely abolished.

8582. That is to say that everything done to an animal for the purpose of advancing knowledge you would forbid?—No, I think I would abolish the present Act. That would leave the experimenter still with his experiment on cat's or cow's milk.

8583. You would let it depend upon the general law of cruelty?—Yes, it would take its place in that way.

8584. Would that help you?—I do not know. I should hope that it would.

8585. I want to test you a little further to see how far we agree. We have had some evidence this morning to the effect that we lose in India 21,000 human lives a year from snake bite. How far in your opinion is it justifiable to experiment on animals with a new suggested cure?—With the virus?

8586. No, that the animal is to be inoculated with the virus, and then the suggested cure is to be applied to see whether it is efficacious?—I would rather go for the snakes.

8587. That is not quite an answer to my question. How far is it ethically justifiable?—Indeed that is the answer. It is very similar to the case of vaccination, and what I said about that was that I would rather go

Rev. J. P. Hopps.

15 May 1907.

for the insanitary conditions. I would turn people's attention away from the cure by inoculation, and turn their attention entirely in the direction in which they can prevent disease altogether. I think that is the safer and more profitable course.

8588. I think you may take it for granted that we cannot exterminate snakes in India, and that you would lose many many thousands of lives before you reduced the number of snakes. Is it ethically justifiable to try a new cure upon an animal for the purpose of saving human life?—I take that case of snakes in India, and I should say I doubt whether what you suggest is the right way.

8589. Take the case of plague, from which we lose many millions; is it justifiable to try any experiments on rats with regard to new cures or new modes of prophylaxis?—Could you confine it to rats. The trouble with me all the way through is that I do not trust the operators. I should go a great deal further in relation to being practically careless about vivisection if I could trust my fellow creatures more. I cannot; I do not believe it is possible.

8590. When you say that you cannot trust them, is it on purely general principles, or because you know anything about vivisectors?—Because of what I know about human nature.

8591. Have you made inquiries in laboratories, or made inquiries from people who carry on experiments?—I do not know them. My knowledge is derived entirely through reading and conversation.

8592. Conversation with whom?—Not with anti-vivisectors only.

8593. Conversation with people who have studied the subject?—Yes. Last Sunday I was talking to a London doctor, himself in favour of vivisection. I get information from these people as much as from others. I do not want to begin inoculation; I dread it—I suspect it.

8594. But you have never made any practical inquiry into the conduct of individual people as to whether they use full anæsthesia or not?—I have had no opportunity of doing so. I do not always know whether any of the friends that I talk with do vivisection or not. I do not know whether my doctor friend that I talked with last Sunday does. I did not ask him.

8595. You do not know whether he has held a licence, or whether he has ever been in a laboratory?—I do not know.

8596. Your distrust, then, is founded upon your general knowledge of human nature, and not on individual inquiry which you have made into the practice in England?—I could not say that. I have been for eight or ten years a rather industrious reader on the subject, reading all sorts of books, and talking with people, medical men and the like, on both sides.

8597. I understand you to say that you equally condemn killing an animal for pure sport as you would for the advancement of knowledge?—No.

8598. Which do you consider the more wrong?—There again you get on to degrees.

8599. Take the case of a good day's rabbit shooting?—I would not like to go rabbiting—that I confess.

8600. Would you prohibit it by law?—Certainly not.

8601. Much greater pain may be caused in that way?—I have no strong opinion about rabbit shooting at all. I have a very strong opinion about what goes on in London and the neighbourhood of London on Sunday afternoons—letting rabbits out of bags for dogs to capture.

8602. And whippet racing?—That is simply vulgar brutality—that is another grade.

8603. In ordinary rabbit shooting you may take it that 5 per cent. of the rabbits are not killed, only wounded?—I am very sorry.

8604. Still, you would not prohibit that by law?—No, I do not think I would.

8605. So that ethically, if I may put it so, it is less wrong to kill or maim for sport than it is for the advancement of knowledge?—No, that is not so, because you leave out there the many other considerations which make habitual vivisection dangerous and cruel.

8606. Which do not make sport dangerous and cruel. I am not talking of racing or anything of that kind; I am talking of sport, in which the object is to kill the animal?—It depends upon what you want to kill it for.

8607. Take foxhunting?—I hate it. The only ethical reason for that is that you must destroy foxes, which would destroy more useful things, but foxhunting, as carried on, is to me most hateful.

8608. It is not the quickest way of killing a fox?—It is most hateful. I almost begin there to want to prohibit it. That is another stage. I resent it very much.

8609. I suppose you know that every horse in England that is not kept for breeding purposes is castrated?—I did not know that. I am very sorry to hear it.

8610. If you look in the streets you will not find a cab horse that is not a gelding in England?—I am sorry for it. I would rather take my chance of the horse.

8611. You know that the operation of gelding a horse is most hideously painful?—I hate it; I loathe it, now that you tell me of it.

8612. Would you prohibit it?—When you ask me whether I would prohibit these various things, what I said was, I would leave all these matters to the common law of cruelty to animals, and then judge every case on its merits.

8613. I daresay you remember that under the Act against cruelty it must be wilful cruelty. The words, you know, are "cruelly tortured"; it does not refer to the amount of pain, but to the intention of causing pain, or negligently causing pain without any useful purpose. Would that help you?—It makes it worse.

8614. Then your only practical suggestion to us is to repeal the present Act and leave the existing Law of Cruelty to Animals to take its place?—Yes, and to amend that as may be found to be necessary.

8615. (*Dr. Wilson.*) You say that you cannot trust men in general who experiment on animals?—That is so.

8616. Supposing that all the witnesses who have been experimenting on animals who have given evidence before this Commission had assured the Commission that their experiments, which it is taken for granted by the law shall be painless, have all been carried out painlessly, could you doubt the statement?—If I knew the men to be honest men and perfectly competent and sympathetic observers, I should believe what they say, and I should be very glad of it.

8617. Do you say that with assurance that you would believe them?—If I knew the men; I would believe any man whom I believed to be honest, competent, and sympathetic.

8618. (*Sir William Church.*) Might I ask you one question more arising out of what Dr. Wilson has just asked you. Why do you feel so doubtful of the honesty of experimenters upon animals?—I do not feel any more doubtful about their honesty than I do about that of other classes of human beings.

8619. Is it not the case that the experimenters who are carrying on experiments on living animals in this country are a highly educated class of men?—Yes.

8620. Men who hold honourable positions?—Yes.

8621. And whose conduct is open to observation by numbers of people daily who work in their laboratories?—Is that so? Do they not do a great deal of vivisection very much left to themselves.

8622. It must be done in a licensed laboratory?—That is all right.

8623. Which is open to their students?—Yes, but the students sympathise, as a rule, with that work.

8624. I am not asking about the students; I am only asking about the facts?—I do not know that it makes any difference that they belong to a high order of professional men and that they occupy honourable positions. We find lapses from righteousness in all grades of society.

8625. But apparently you have spoken this afternoon as if you could not trust any of these gentlemen?—Not "any." I never said any. I do not trust, in the present stage of social development, any order of men with doubtful powers. That is so with soldiering, and it is so with all kinds of occupations.

8626. Do you mean that these gentlemen deliberately break the law?—No, I do not. There are very many people who, in the pursuit of money, for instance, get themselves into entanglements.

8627. In the pursuit of money are they working in a licensed place, and probably in the presence of a number of students, or, at all events, of their assistants, who are aware of all that they do?—Yes, and more, because they work in the City of London under the inspection and observation continually of hundreds of clients and fellow-financiers.

Rev. J. P. Hopps.

15 May 1907.

8628. Have you not given evidence to-day on what you think is the case on many points without having made any inquiries as to whether it is so really?—I cannot say that; I do not admit that at all.

TWENTIETH DAY.

Wednesday, 29th May 1907.

PRESENT:

The Right Hon. The Viscount Selby (*Chairman*).

Colonel the Right Hon. A. M. Lockwood, C.V.O., M.P.
Sir W. S. Church, Bart., K.C.B., M.D.
Sir W. J. Collins, M.P., M.D., F.R.C.S.
Sir J. McFadyean, M.B.
Sir M. D. Chalmers, K.C.B., C.S.I.
Mr. A. J. Ram, K.C.
Mr. W. H. Gaskell, M.D., F.R.S.
Mr. J. Tomkinson, M.P.
Mr. G. Wilson, LL.D., M.B.
Captain C. Bigham, C.M.G. (*Secretary*).

The Rev. Lionel Smithett Lewis, M.A., called in; and Examined.

8629. (*Chairman.*) You and Miss Woodward, I believe, have been deputed by the Church Anti-Vivisection Society to present their views to this Commission?—That is so.

Rev. L. S. Lewis, M.A.

29 May 1907.

8630. And I see that you have sent us in a *précis* of your evidence. You speak entirely on what I may call the ethical question?—Entirely, except in so far, of course, as I give some evidence of the statements I make. I make a statement in the last paragraph, paragraph 13, that the logical outcome of experiments on animals is experiments on man, and that the right to perform such has been claimed and carried out. In making a statement like that, I should put in some facts.

8631. You deny that right?—I deny that right.

8632. That is all; it is only stating the converse view?—My evidence is on the ethical side entirely.

8633. We have had a good deal of evidence on the ethical question, and we all of us feel the importance of hearing it; but the Commission have been considering that matter, and I think it is right that I should say that they think that they have heard it at a length from some witnesses which makes it unnecessary for them to hear at the same length from others; they have given a very free hand to some witnesses as to the length of their evidence, but the points are really short and capable of being shortly put, and if I may say so, you seem to have put all the points (almost all of which I am bound to say have already been put before us very tersely and clearly in your *précis*; and what I propose to do is to take that statement of yours as being a statement of the views of the Church Anti-Vivisection Society. I do not think we ought to call upon you or invite other witnesses to enlarge upon this question, because it really comes to our hearing a certain number of speeches in favour of certain opinions. We want the opinions, we want to know how far those opinions are backed, but we are all of us, I hope, people of some common sense and experience in the world, and when we have heard these propositions stated fully two or three times, it is almost as much as our minds will absorb on the same point, and we do not gather much by repetition. That certain considerable classes of the community agree in those views, and that they should put their views quite shortly before us in support of the general principle, we are quite ready to admit, but many witnesses have given us a *précis* and have followed it by long written statements which I do not think, having regard to the time which should be taken in this Inquiry, we can continue to hear. Therefore, if you will allow me, I will ask you, first of all, what is the Church Anti-Vivisection Society, what is the nature of the body, how many members does it contain?—The total clerical members in the last report were 375, the total lay members 496, making 871 in all.

8634. Do they consist of all classes, or mostly of what we may call the more educated classes?—They consist of all classes, but mostly of the educated classes.

8635. Then, so far as I am personally concerned, but without prejudice to any other members of the Commission who may wish to ask you questions, I would ask you: Do these views which you have stated in the 13 paragraphs of your *précis* express fairly the views of the Church Anti-Vivisection Society?—I believe so. I sent my evidence in to them and they forwarded it; therefore I suppose that they approve of it.

8636. And I need not say that they are views which you yourself hold also?—Most strongly. My statement on the morality of vivisection is as follows: (1) Before we argue as to whether an act pays, we must first consider whether it is right. (2) Power of enjoyment shows the intention of the Creator that the possessor should be happy. (3) Power of enjoyment is the most dominant feature in man and beast. (4) Pain is intended to give warning that continuation of an act will prevent well-being and enjoyment; that is, pain is intended to preserve the *individual*, to promote his ultimate enjoyment. (5) An action involving temporary pain inflicted on another may secure to the sufferer greater physical good than would otherwise accrue. (6) An action involving temporary pain inflicted on another may secure to the sufferer greater moral good than would otherwise accrue. (7) It is immoral (because contrary to the primary intention of pain) to inflict pain unless it is honestly believed that the pain will procure, at least in part, the moral or physical good of the individual sufferer. (8) The right to take life does not imply the right to make living unendurable. (9) To control one's aversion from causing suffering, and to inflict temporary pain on another for the sake of future gain for the sufferer ennobles; to inflict pain on another unless this motive is present is cruel, and hardens and degrades the one inflicting it; to profit knowingly by pain inflicted on another where this motive is absent makes the person benefited a coward. (10) Because we see suffering all around us, to think that we may blindly inflict it is both foolish and impious. It is as if a great surgeon performed an operation for the benefit of the sufferer, and a

Rev. L. S. Lewis, M.A.

29 May 1907.

mischievous ape who had witnessed it attempted to imitate his action without his knowledge. (11) The dog or cat, etc., gives up its wild nature, because it has learned to trust man; and this trust is betrayed, and by an act of treachery, when the victim is placed upon the vivisectional table. (12) I have tried to prove that vivisection by its nature is a perversion of the intention of pain (and therefore immoral), cruel, and cowardly, and that, furthermore, it is treacherous. That being so, while I might painlessly sacrifice the lives of many animals to save one valuable human one, I would not have one mouse painfully vivisected to save the greatest of human beings nor the life dearest to me. (13) The logical outcome of experiments on animals is experiments on man. The right to perform such has been claimed and carried out. A race of medical men hardened by vivisection is a public menace. The rights of animals rest on exactly the same foundation as the rights of man—justice and mercy. The temptation to a man who has hardened himself to make experiments on animals which were not for the good of the sufferer, to make experiments on human patients which are not for the good of the sufferer, must be very great. He has blunted his moral sense by inflicting pain in a way which was exactly opposite to the intention of pain. He has broken down the one safeguard which separates humanity from cruelty. Without the knowledge of God he is impiously claiming the power of God to inflict pain where he sees fit.

8637. (*Sir William Church.*) With respect to paragraph 12, have you any special object in choosing the mouse as an animal?—No object whatever; simply to take some very small creature which is not valued very much by most people (most people try to get rid of mice), and it occurred to my mind as an illustration.

8638. (*Chairman.*) To put your case stronger?—That is all.

8639. (*Sir William Church.*) You were not aware that there has been a great deal of experimentation of late upon mice with regard to cancer?—That did not enter into my mind when I wrote those words.

8640. You were not aware, either, that mice are very much used for diagnostic purposes?—No, I was not. That would not make any difference.

8641. As discriminating between different diseases?—No, but that would make no difference.

8642. (*Colonel Lockwood.*) You simply chose the mouse as the humblest representative of life?—I will not say the humblest, but as one that people do not value much.

8643. (*Sir William Church.*) Do you think we are authorised in killing rats and mice at all?—Certainly, when it is necessary; but, in my view, the death should be instantaneous. I think, for instance, the tooth trap, and I think that ordinary trap, the cage trap, are simply barbarous. I think the only trap that should be set is the one that breaks the back at once. As you ask me that question, I may say that I have never had a trap set in my own house, and if people would only cover up their food, which is very much more healthy for them and much more cleanly, they would not need to set mouse traps.

8644. Then, to protect your food, you think you may take proper steps to clear your premises of mice and rats?—As I have said, I think, in my *précis*, I admit the right of killing; but the right of killing does not imply the right of making living miserable. I think I can illustrate it in this way. Rightly or wrongly, at present the laws of this country think that it is permissible to hang a man for murder, and when people consider there has been a gross murder, the papers do not make a great stir about it; but if we read to-morrow morning that a prisoner who committed a murder and was condemned to death had been tortured in his cell, I do not believe there is a single paper that would not take it up; and from that I argue that the power to kill and the power to make living miserable are two very distinct things.

8645. Do you approve of the destruction of rats with the object to prevent the spread of plague?—I hate killing unless it is an absolute necessity. I see no sin, when people are absolutely convinced that plague is spread by rats, in their being killed. I do not say I believe that the evidence is sufficient; as one of the public, who form the jury in those things, I am entitled, of course, to my opinion, whether we have not got a craze for killing everything. I remember quite recently somebody wrote and suggested that all the pigeons in the City should be killed, because they deposited germs. One begins to wonder what you can do for fear of germs.

8646. But might I ask you, do you consider that we have the right to kill rats or other animals to prevent the spread, or, we think, with the object of preventing the spread, of disease in man?—I think that to kill painlessly for that object is no more sinful than to kill for food.

8647. Is it wrong to kill for food?—I think not.

8648. But you think that, although it is right to try and protect ourselves in this way, it is not right to take the life of an animal for the sake of investigating our views as to the production of disease?—I have never objected to an animal being killed for that purpose. I object to its being kept alive in suffering, which, to my mind, is a quite distinct thing.

8649. But might I ask you just to explain what you mean by being "kept alive in suffering"?—Of course, I am not here to give scientific evidence, but I felt that if I was going to give ethical evidence I must be able to give some reasonable cause for holding the opinion that vivisection inflicts pain; and, consequently, I can refer to evidence already given.

8650. I am speaking with regard to these mice. The mice are not used usually for vivisection in the way of demonstrating organs or anything of that sort; they are chiefly used, as I say, now largely in the investigation of cancer, and they are largely used as a means of differentiating disease by means of inoculation?—We have the evidence given before this Commission already, that very great pain sometimes—I can give you chapter and verse, I have it down here—results from inoculations. For instance, Mr. Thane, the inspector, at Question No. 457, says that under Certificate A, inoculations will cause, his words are, "great pain and suffering sometimes, and he gave as an instance the injection of tetanus toxin, infection with plague, and also the insertion of certain drugs; therefore, as I object to animals being kept in suffering, I most strongly object to a mouse being treated in that manner.

8651. (*Sir William Collins.*) In your paragraph 12 you state that while you might painlessly sacrifice the lives of many animals to save one valuable human one, you would not have one mouse painfully vivisected to save the greatest of human beings nor the life dearest to you. You appear there to draw a distinction between painful and painless vivisection?—I want to be very exact in what I say; that is why I put in that word "painfully." If you want to elicit my opinion upon that point, I think that under the present safeguards it is impossible to know what are painful vivisections and what are not; and when we consider what happens in slaughter-houses, which are so much more open than laboratories (and in every case when a man has animals within his power), what things can go on there, certainly in a closed laboratory, I think the risk is enormous of having vivisection carried on at all; but if it were possible to be sure that an animal was completely under anæsthesia, and was destroyed for certain before it recovered, then I should have no more objection than I should to killing an animal for food. But personally I may say this. I would not hand myself over to vivisectors under those circumstances, and, therefore, I would not have any animal handed over to them. I would not trust any body of men of any calling with full power behind closed doors, especially in the case of those who cannot speak for themselves and tell us afterwards what they have suffered. That is my view.

8652. My question merely was: Am I right in thinking that you draw a distinction between painful and painless vivisection?—If it was possible to get painless vivisection I should not disapprove of it, because it is the infliction of suffering to which I object. I want the total abolition of suffering.

8653. I thought your paragraph 12 implied that you considered there was such a thing as painless vivisection?—I have never said that I am satisfied that there is such a thing. I wanted to be very exact, and I wanted just to make quite clear my point, that it is the living in suffering that I object to—that we should inflict it upon them.

8654. Do you doubt that there is painless surgical operation?—Personally I have never known a person who was operated on (I believe the right word is aseptically) but what they have felt pain afterwards.

8655. But do you doubt that under anæsthetics a surgical operation may be performed of considerable magnitude, and the patient subsequently state that he has felt no pain?—Really I am here to answer ethical questions, and that is a scientific question, which I do not think it is quite fair to put to me; I did not come to give scientific evidence.

8656. (*Chairman.*) It is hardly a scientific question to ask you, do you think that if a boy or a grown-up person has a tooth taken out under gas or ether that is a painless operation?—If the questioner in asking me do I believe that there can be complete anæsthesia of human beings, of course I do, the same as any other reasonable person twelve years old would probably admit.

8657. (*Sir William Collins.*) I will not trouble you further on that. I will proceed to your paragraph 13, which deals more particularly with the moral aspect. I see you state that the logical outcome of experiments on animals is experiments on men, and the right to perform such has been claimed and carried out; that a race of medical men hardened by vivisection is a public menace; and that the rights of animals rest on exactly the same foundation as the rights of man. Do you put the rights of animals as regards either destruction or, as the term is frequently used, exploiting them, on the same level as the rights of man?—I did not say that the rights of animals are of the same magnitude as the rights of man. I said that they rested on the same foundation. Two trees of very different size may grow upon the same soil.

8658. Am I right in thinking that by that you mean that there is a difference in degree, although they may be of the same kind?—Certainly. I do not think I have the right to kill my brother man for food, but I think I have a right to kill animals for food.

8659. Then I take it that your opinion is that the rights of animals differ in degree as regards their use by man from the rights of men?—I do think so; at the same time I would just like to read this—they are the words of Jeremy Bentham on the rights of animals: "The day may come when the rest of the animal creation may acquire those rights which never would have been withholden from them but by the hand of tyranny." I am not quite sure of the next word, which was copied for me, but I could not read the person's writing. "The French"—I think it is—"have already discovered that the blackness of the skin is no reason why a human being should be abandoned without redress to the caprice of a tormentor. It may come one day to be recognised that the number of the legs" (again I am not quite sure that is the word; I think it is) "the callosity of the skin, or the termination of the *os sacrum* are reasons equally insufficient for abandoning a sensitive being to the same fate. . . The question is not, can they reason, nor can they talk? but, can they suffer?" That is taken from the works of Jeremy Bentham, published under the superintendence of his executor, John Bowring, volume 1, pages 142-3, in a note. It is on the subject of An Introduction to the Principles of Morals and Legislation.

8660. That quotation would appear to contemplate a stage in the evolution of morals which we have not yet attained to, would it not?—We have not yet attained to that, but we have attained to it very much more than when that was written, I hope and think. For instance, it was practically in the Victorian era that people realised that an animal is entitled to wages for its work, is entitled to food and shelter, and if a man neglects those, the law of the land will deal with that man.

8661. On what moral principle would you differentiate between, as I understand you to say, the legitimate sacrifice of animals for food and possibly also for clothing and for convenience, and yet forbid it for the purpose of advancing knowledge or for an endeavour to improve medical treatment?—The great distinction that I draw is this. We have the right to take life when necessary, but to torture an animal, to use a strong word, or, rather, I prefer to say, to make living miserable, is a perversion of the intention of pain. It is perfectly clear to my mind that pain was given for the preservation of the individual, and I think we can see that in the case of fire. Supposing we had not felt pain from fire, we should have very often run in such danger that we should have been burnt up or seriously maimed before we knew of the danger; but the feeling of pain is a warning to the youngest child that a thing is to be avoided; and those of us who are older and have learnt that lesson, if we suddenly get near a dangerous flame, and get warning from the heat of pain we feel, cease to do that which might have injured us. That seems to me to be the intention of pain. In my point of view every wrong is an excess or perversion of the use of a right power. I think we can see that practically every vice is an excess or perversion of a virtue. The infliction of suffering in a manner contrary to the intention of pain (the preservation of the individual) is a perversion of a power, and therefore a wrong, and nothing can make it right.

8662. I notice that you used with some hesitation the word "torture." Making another quotation from Jeremy Bentham, perhaps it may be regarded as a question-begging epithet. It implies, does it not, needless cruelty or intentional infliction of pain?—In that case, if that is your definition, I should most certainly call vivisection, in every case which inflicted the slightest pain, torture, because it is the perversion, in my opinion, of the intention of pain, which was to preserve the individual; instead of which the experiment is used to inflict pain on the individual, not even in part for its own sake, but absolutely for others. I hold that to be immoral, because I consider it to be a perversion of the intention of pain.

8663. (*Sir John McFadyean.*) In paragraph 7 I understand you to hold that the infliction of all pain on animals is immoral unless it is for the benefit of the individual animal?—In my copy of the *précis* I have inserted before the words "the moral" the words "at least in part." The passage runs:—"It is immoral (because contrary to the primary intention of pain) to inflict pain unless it is honestly believed that the pain will procure, at least in part, the moral or physical good of the individual sufferer."

8664. You are aware, of course, that for the purpose of improving the quality of beef and mutton and pork farmers and others who own animals habitually submit them to a very painful operation, to unsex them. Do you think that is immoral?—I have thought of that question for some time. To begin with, I have not the slightest doubt that in many cases that operation is performed when it need not be, and, knowing what human nature is, there is not the slightest doubt that it is very often cruelly performed; but, of course, a thousand wrongs do not make a right, and I think one of the great values of attacking one wrong is that the people you attack always draw strong attention to another, so that the field of attack opens out enormously. You ask me whether I think it wrong. I have to apply, of course, my principle. My principle is that you have no right to inflict suffering unless it is at least in part for the good of the being upon whom it is inflicted. The first thing I should have to decide is this: is it not in part for the good of the animal that this pain should be inflicted? So far as I know it seems to me that many animals lead a much happier life because that operation has been performed than they would have otherwise. If you can convince me that that is not the case, I should simply oppose it absolutely, because I cannot alter principles to fit facts; facts must be altered to fit principles.

8665. I suppose you do not seriously contend that the intention to benefit the horse or the ox or the pig that is unsexed by that operation has ever entered into the farmer's mind?—It may not have entered into the farmer's mind, but there is someone above the farmer, and that is the public; and there are many things which are permitted, whatever the original inflictor's intention may be, because the public can see that it is not without good to the being upon whom it is inflicted. That would be my answer.

8666. Do you discriminate between the lower animals and man in this connection?—In what way do you mean?

8667. I mean in connection with the operation of unsexing?—It should not be done, of course, except for the person's good.

8668. Do you suggest that it is for the good of either a human being or an animal to be unsexed?—In the case of animals, I am really not an authority upon a point like that. If it violates that principle which I laid down, I should strongly oppose it; but I am of opinion that a great many horses lead happy lives doing useful work, being loved and well treated, which probably would not lead such happy lives if that operation was not performed.

8669. Why should that be?—Because people, I understand, say it is impossible to use them unless that operation is performed.

Rev. L. S. Lewis, M.A.

29 May 1907.

8670. I am not speaking about the using: I am coming to that presently; I am speaking about those animals which are kept for food purposes and killed for food purposes?—I do not know how far it is a question whether they could be kept at all in the country fields.

8671. Of course they could?—In that case, certainly, I think it wrong. If your facts are right, then I think the operation wrong.

8672. But supposing it is a mere matter of convenience to the owner; that is to say, that it would be more difficult to keep them in fields and so on, but not impossible, at greater expense, in your view that would not justify these operations?—Not if it causes great suffering.

8673. It is a matter beyond any dispute that many millions of animals are subjected to these painful operations in every twelve months, so that the amount of pain inflicted in this way on the brute creation must far exceed the whole amount of pain that is caused through what is called vivisection. Would it not be better to attack the greater evil first?—Everybody who supports an evil thinks somebody else's evil greater.

8674. But how do you measure the magnitude of an evil which consists in inflicting pain on animals?—You measured it; I did not. You said the greater; I did not.

8675. I did. I am asking how you measure it. You objected to my measurement; how do you measure it?—I attack all cruelty wherever I find it. I am not only an anti-vivisectionist; I attack all cruelty.

8676. Have you ever attacked this particular form of cruelty before?—It has not been brought to my mind. I have thought of it for some time—for about twelve months or so—and I have not got very much knowledge. I may tell you that I spoke to a doctor about it not long ago. I asked him my point. I said, "Is it not sometimes performed for the good of the animal itself?" "Oh, undoubtedly," he said. Like every other form of cruelty, like cruelty in a slaughterhouse and everywhere else, I abominate it. I attack every possible source of cruelty. You speak about attacking it. It is quite right; it would have to be done; we must have no squeamishness; but it is a very difficult subject to tackle in public.

8677. But that need not restrain you?—No, quite so; and every influence I can possibly bring to bear upon everybody, I would on that subject.

8678. So I understand that if your efforts in connection with the question of vivisection were successful you would probably in the next place try to bring about legislation to suppress these practices which farmers carry on?—You greatly mistake my attitude. I never wait until one evil is gone before I attack another. I do everything in my power as I see the ability to do so, to attack all evils at the same time. I prefer not to wait till one evil has gone to attack another.

8679. Of course, if you are going to do that immediately——?—But I am not yet convinced that it is an evil so great as you say. I am in the state of a person who begins very gravely to suspect and to fear.

8680. But you must have misunderstood me. I did not intend to express an opinion such as you ascribe to me. I was not giving an opinion as to whether it is an evil. I do not myself believe it to be an evil. I merely wanted to find out whether you were consistent or not?—I thought you called it the greater evil.

8681. Oh, no?—I thought you asked me why I did not attack the greater evil rather than vivisection.

8682. From your point of view it was an evil; I prefer to describe it as so much pain. I said that these operations involve much more pain than all the operations conducted by vivisectors?—That is a matter of opinion.

8683. You are not of that opinion?—I say that is a matter of opinion. I cannot give an opinion on that.

8684. But if I tell you that there are 10,000,000 animals on which the operation of castration or ovariotomy is performed in full consciousness every year, would you doubt it?—I say that of course I should want to know at what age it was performed; whether the animal suffers really at that age. I should be afraid it is so, and if the animal suffers, certainly it ought to be compulsorily under anæsthetics; and if anyone says that there are not enough anæsthetics to do so, I have not the slightest doubt that when the demand comes the supply will come also.

8685. That was not the question. It was a question of the comparison of the amount of pain that was inflicted by men. I think, in paragraph 9 of your *précis*, you indicate that in your opinion it is cowardly to share in any advantages which may be derived from inflicting pain on the lower animals when it is not intended for their own good. Are you a vegetarian?—I am not.

8686. Then you will hardly deny that you do share in an advantage which is attained by the unsexing of pigs and rams and bulls, unless you habitually ask for bull beef from your butcher?—I do not think you quite understand the words of my *précis*, "To profit knowingly by pain inflicted on another where this motive is absent makes the person benefited a coward." What I there want to bring out is this: I have in my mind such things as this: Supposing I was suffering from diphtheria, there is nothing in the world that would induce me to use or have used on me anti-toxin, because I believe the production of anti-toxin to be a sin. What I mean by being cowardly is this: I look upon vivisection in this way. Every now and then we hear with great pride, coupled with great sorrow, of some disaster, where, when every legitimate means have been taken to save the crew and passengers, when nothing more can be done, the women and children are put into boats and the men go down at their posts. I do not think anyone will say that that is done because the lives of women and children are necessarily of more value than those of men; it is because they are weaker; and therefore when everything lawful has been done the men stand at their posts bravely and go down. Now, some years ago there was a most lamentable incident which happened at a charity bazaar, where the men lost their heads and beat the hands of women and children, making them loose their hold on the balustrade so that they might save themselves.

8687. (*Colonel Lockwood.*) That was in Paris?—It was. That was an instance of panic. Now, vivisection is permitted, to my mind, for two reasons: partly because people fear death, and partly because they fear suffering, and, instead of being like the sailors at their posts when inevitable suffering or death comes, and they have taken all legitimate means—instead of saying "This has been sent to me, and I must bear it with fortitude as a man and as a Christian"—they turn to what I consider unlawful means in panic. That is what I mean by its being cowardly to knowingly use a thing which is the product, absolutely the product, of what is unlawful. But now let us suppose for a minute that a lawful thing is vitiated by the sins of people, what we have to try and do is to get that sin put a stop to. But we need not cease to do a lawful thing. It is lawful to eat meat; it is, therefore, our bounden duty to see that the animals are killed as painlessly as possible. And if your facts are perfectly correct it is also our bounden duty to do our best to see that these animals are operated upon in the way you mention, under anæsthetics, but until that is done, because it is the vitiating of a lawful deed, I do not think we are compelled not to eat meat at all when it is part of our nature to eat meat.

8688. (*Sir John McFadyean.*) I am afraid really you misunderstand my question, which is: Do you consider it your bounden duty to abstain from eating the meat of these castrated animals, because it is undoubtedly better meat, which sells, I suppose, 25 per cent. dearer at the butcher's shop; it is an advantage, that is to say, in purchasing meat for one's diet, not merely from a nutritive point of view, but from the point of taste. Do you consider it your bounden duty to abstain from it?—If the meat itself was absolutely the product, then I should consider it my duty; but there will be meat whether that cruelty, if it be cruelty, is performed or not, and I consider that that makes a very great difference. I say, there is meat. I have animal teeth given me to eat that meat, and I am not going to abstain from eating that meat because somebody else has prepared it in a wrong way. What I will do is to try and get that wrongful preparation of that meat stopped. That is my view.

8689. Are you entirely opposed to field sports in consequence of the pain they inflict upon the lower animals?—No, but I think to take a pleasure in them is simply horrible. I think animals must be killed,

but how anybody can take pleasure in going and killing anything is simply past my understanding.

8690. I was not concerned with that at the moment. I wanted to know whether you think field sports which involve the infliction of pain on animals obviously not intended for their own good, are moral or immoral?—The animals have to be killed.

8691. No, not necessarily; they are bred on purpose to be killed many of them. Will you deal with those cases?—Take, for instance, foxes. It is plain that foxes would have been exterminated had it not been for hunting, therefore, as the fox enjoys its life, hunting has been a benefit to it.

8692. (*Chairman.*) Take pheasant shooting?—In the old-fashioned way, when a man went out with his dog to shoot——

8693. No, take the present time?—Do you mean, do I approve of battues?

8694. I mean pheasant shooting as carried on at the present time?—Personally nothing would induce me to take part in it, any more than I would go to a butcher's shop and slaughter a beast for my food. I know many sportsmen who are the kindest hearted men, they have certain rules and regulations, and they have a keen sense of fair play, but personally the way in which I look at it is this: There are many offices of life that have to be performed. I do not intend to perform them as long as somebody else can be got to do it. For instance, sewers have to be emptied. Not one of us at this table, I suppose, would wish to go into them. I venture to say, without speaking in the slightest degree contemptuously of sportsmen, that personally I look upon sport as one of those occupations I myself cannot understand the pleasure of.

8695. (*Sir John McFadyean.*) What is your defence of the pain inflicted by breeding pheasants and shooting them afterwards?—I do not understand the pain inflicted in breeding them.

8696. I did not say so. I said, in breeding them and shooting them afterwards. I mean that they are expressly bred in order to furnish sport with the gun. Is it your view that it is necessary to have that carried out?—I doubt the statement, to start with, that they are only bred for that. I think that many people like to see them about the place, because they are extremely beautiful.

8697. (*Chairman.*) You might leave out that small percentage and deal with the 95 per cent. where they do it for sport?—May I have the question once again?

8698. (*Sir John McFadyean.*) I understand you to class the shooting of pheasants and the infliction of pain which it involves, with such things as emptying sewers and slaughtering cattle in slaughter houses—that is to say, things necessary, but things you would not like to do yourself. I say, is that so; do you classify it with those things and justify it on the ground that it is necessary?—Never mind motives for breeding pheasants; as long as pheasants are in the world, and are an article of food, it is no more cruel to kill a pheasant by shooting it than it is to kill cattle in an abattoir. Personally, if you gave me my chance as a fox or a pheasant, or as an ox to be killed in a slaughterhouse, I would choose to be a fox or a pheasant.

8699. Is the use of the whip and the spur on horses justified under your code of ethics?—Certainly, because to be unrestrained, and to have one's way completely is bad for everybody. If you look at my *précis*, paragraph 6, I say: "An action involving temporary pain inflicted on another may secure to the sufferer greater moral good than would otherwise accrue." That will cover all punishment.

8700. I am not speaking about the use of the whip and spur as punishment, but as a goad to make the animal go quicker; that is the ordinary use of the whip and spur. Is that represented as being for the animal's good?—A man who uses his whip on an animal that is doing its best is a man who is not inflicting punishment; that is not punishment. If he uses his whip to make the animal go quicker it means that he thinks it can do more; he either does it by simply moving his whip, the mere movement is enough if the animal is willing; but if the animal is lazy, and needs a little punishment, that is punishment.

8701. I ask you to consider the case where an animal is not lazy, and is going at eight miles an hour, and the driver desires him to go at ten miles an hour. That is hardly for the animal's good. I want to know, is it justified?—My answer is simply that if the horse is going as well as it can the man has no right to inflict punishment. If the man wants it to do better, if it is a willing horse he does not have to hurt it with the whip, but if it is an unwilling horse then a little punishment is needed, and if he gives it properly there is no cruelty.

Rev. L. S. Lewis, M.A.
29 May 1907

8702. But there is no horse willing to go its utmost speed?—I do not know about that.

8703. Suppose a horse going eight miles an hour and the owner, for his own convenience, wants to make it go twelve miles an hour, is he justified in using the whip and spur?—I am astonished at your statement that there is no horse willing to go at its utmost speed. There are some horses you can hardly hold in.

8704. I admit the exception—1 per cent., perhaps. Please deal with the average?—I think the proper punishment of animals is lawful.

8705. It is not punishment at all. I ask you to assume the case of a horse that will go without punishment at the rate of eight miles an hour, and the owner, for his convenience, desires it to go at the rate of twelve miles an hour. Is it immoral for him to use the whip and spur?—If going ten or twelve miles an hour will inflict injury upon that horse he is wrong, but it is no more wrong to induce the horse by moving the whip, or a painless flick of the whip, to go faster than to encourage it by word of mouth. A willing horse will go by mere sound.

8706. But always assuming that he has used the whip in such a way as to inflict pain, which is quite a common thing, or that he has used the spur in such a way as to inflict pain—very little pain, I admit, but still much more than is inflicted by some vivisection operations—is that immoral?—The horse is a servant; it is paid wages to do certain work, and if work is not demanded from that horse which it is unable to do there is no cruelty in inducing it to do it. If your means of communicating with that horse which that horse best understands is your whip, you are simply making a justifiable demand upon it; you are not asking it to do too much. There are many horses that you do not have to touch with the whip.

8707. In this case you draw a distinction between man's duty to his fellow-man and man's duty to his fellow-creatures, because you would hardly justify the use of a whip on a paid servant who is not working to the satisfaction of his employer?—Perhaps you will forgive me for pointing out that there are different means of communication. There are three forms of speech: There is articulate speech, there is tone, and there is gesture, and with the animals it is tone and gesture that generally convey our meaning to them, and therefore just as we have practically by tone and gesture to convey it to them, so it may be necessary to convey it by the whip. And, after all said and done, I expect most of us round this table, when we were boys, felt the whip when we were lazy. I do not know that there is any cruelty in that. I should put animals in the same category as children.

8708. (*Chairman.*) We are getting a long way, I think, in these refinements about cruelty—about how far we are entitled to whip a horse or not. You called it punishment just now; but I did not know that the horse had a moral duty, for the breach of which it ought to be punished, from your point of view.

8709. (*Sir Mackenzie Chalmers.*) Have you a list of your Council. Would you hand us in a list?—Here is the sixteenth report (*handing in the same*).

8710. Are you a member of the Council?—No, I am an ordinary member of the Society.

8711. But you were chosen to represent it?—Yes.

8712. Are you a beneficed clergyman?—No; for the last seven years I have been a curate in the East-end of London.

8713. As you know, the Commission is appointed to investigate the operation of the Act of 1876, and to see whether any or what alterations are required. What does your Society suggest in the way of altering the existing law. That is the point we have to consider?—I am here to give moral evidence only. It would be better to ask other members as to that.

8714. But in consequence of the moral evidence that you give do you suggest any legislative changes?—That is not in my *précis*. I was told I was to keep myself absolutely to moral evidence. I prefer to do so.

8715. Somebody else will answer that?—I may just

Rev. L. S. Lewis, M.A.

29 May 1907.

say for a minute that the Society itself is pledged to try and obtain the total abolition of vivisection.

8716. That is what I want to know?—I thought you wanted a technical point.

8717. No. You want to abolish vivisection altogether?—That is the aim of the Society.

8718. And by vivisection what do you mean, because the word "vivisection" does not appear in the Act. Do you mean only experiments causing pain, or all experiments on animals?—Personally, I have explained that I want the total abolition of pain.

8719. For instance, feeding experiments and any experiments which might be useful but do not cause real pain you do not object to?—It is very difficult (I am talking for myself, not for the Society) to draw the line apparently, and some of the questions asked in Parliament and correspondence with the Home Office arising therefrom have shown the extreme difficulty there seems to have been in drawing a distinction between some experiments inflicting pain and some not, and, personally, the very thing which a vivisector has called the mere prick of a needle is one of the things I am most opposed to—namely, inoculations. I think the suffering is very great after them. I have already read one statement which I brought here among others.

8720. They may or may not be followed by great pain?—Sir James Russell, the Assistant-Inspector, at Question 543, before this Commission, spoke about a cat, for instance, which suffered "severe pain" after the insertion of Daboya venom. He spoke about pain from drugs. He said that some rabbits suffered "much pain," and then he spoke of some rats as "miserable and dying evidently in suffering."

8721. I asked those questions for this reason: Rule 2 bases the League's action upon the conviction that morality and religion have the right to impose and maintain limits upon research and experiments in human nature. I did not know whether you meant that there ought to be restrictive legislation, as there is at present, or whether you would carry that restriction much further and abolish experiments on animals for the purpose of research?—The object of the Church Anti-Vivisection League is total abolition. I do not believe there is any anti-vivisectionist living who would object to an animal being experimented on and destroyed without any suffering.

8722. If he was sure that anæsthesia was complete?—Yes. But many antivisectionists say what Lord Shaftesbury said—I think I have Lord Shaftesbury's words here, and I should like to quote them; he said, "We are bound in duty, I think, to leap over all limitations and go in for the total abolition of this vile and cruel form of idolatry, for idolatry it is, and like all idolatry, brutal, degrading and deceptive." That is an extract from a letter to Miss Cobbe.

8723. Now, as regards the moral question, I want to ask you this. You are aware that a large body of opinion, opinion of men whom we highly respect on moral grounds, thinks that vivisection is justifiable?—Yes, I am aware of it.

8724. Practically the whole opinion of the medical profession substantially?—We have had some great exceptions, and it is very hard for a man to swim against the prevailing current of his profession; therefore when you say that you have practically got the whole it makes those exceptions you have of very great value.

8725. What I was coming to was this: We have, at rate, in evidence here, conflicting moral views. What do you suggest as the objective test for the Commission to apply. We have had evidence on both sides here from the moral point of view. What is the Commission to take as a test?—What I have tried to lay down; that I consider we can abundantly see that the intention of pain was to preserve the individual, and therefore, unless that partly enters into the infliction of pain, pain ought not to be inflicted. But I say that vivisection is a perversion of the intention of pain, and therefore immoral. Sometimes I have heard people liken vivisection to the Inquisition. I think it does a very great injustice to the Inquisition; because, disastrous as the Inquisition was, they at least had this in their minds, that they believed that the pain they inflicted was for the good of the soul of the person upon whom it was inflicted. No such claim can be made for vivisection.

8726. That hardly answers my question. Is there any objective test by which we, as a Commission, can apply a standard when we have these conflicting views of morality. The vivisectionists, as I will call them, the people who justify experiments on animals, say that the infliction of pain is justified when there is an adequate return for it?—You have said that the greater part of the medical profession is in favour of vivisection. The medical profession are not specialists on the moral question. That is not their province; and I would refer you to the great thinkers of the world, Shakespeare, Browning, Tennyson, Dr. Johnson, Voltaire; in the law, Lord Chief Justice Coleridge, Lord Brampton; and I have with me (I thought, perhaps, it would be better to bring some; I should like to read them, if I may) the opinions of those men and others.

8727. I only want to get the principle?—Exactly.

8728. (*Chairman.*) That hardly arises out of the question. We have had all the opinions of those who have expressed opinions?—My point is this, that on the one hand you have the doctors, who are not, it is not their province to be, specialists in morality; they plead as to the utility or not; it is men who are moralists who plead as to the morality or not; the jury is the public. I want to show that besides those great thinkers I have mentioned, I have the opinions of two Bishops of Durham, Drs. Westcott and Moule, Cardinal Manning, and Bishop Mackarness of Oxford, Bishop Moorhouse of Manchester, Bishop Harold Browne of Winchester, as moralists strongly condemning vivisection, and if I wanted a guide for morality I should go to those. If I wanted a guide for utility I should go to doctors.

8729. I was not objecting to your stating that there were these number of people expressing an opinion; I rather objected that we should hear all their opinions read out?—They are rather strong and important. I do not know if I may read any of them.

8730. (*Sir Mackenzie Chalmers.*) We have practically to recommend legislation. In recommending legislation you say that we ought to consider the opinion of certain people who have studied morals?—Then do not you think I have the right to ask, as I am giving evidence on the question of morality, that you shall hear very short statements by those very great specialists in morality, the bishops.

8731. I want simply to get at the test which we have to apply?—I should be guided best in my morality by moralists, and in my idea of utility, by doctors.

8732. By bishops?—Yes, and the other great men I have mentioned.

8733. I will take that. I only wanted to know what your test was. There are one or two tiny points arising out of your evidence as to which I just want to see how far you go. You said that you would refuse to be treated with antitoxin for diphtheria?—Yes.

8734. And you think it really cowardly to adopt a remedy which might possibly save your life because you think it is wrong?—Some years ago I thought I was going to have diphtheria. I went back and wrote down a request and left it addressed to my father that if I became unconscious he was not under any circumstances to have antitoxin applied.

8735. Now, I want to put this question to you: I suppose most of us have seen children die from diphtheria—helpless children. There is not great courage in letting a helpless child die from diphtheria. Do you think you are justified, to save the life of a helpless child, in using antitoxin or not?—I would not allow my own child to have antitoxin administered to it to save its life. You should not do evil that good may come. The thing is wrong in itself; it would not exist in the world if it had not been for vivisection; it is not the sort of thing that might have been discovered by something else.

8736. That is quite true, as an instance?—Therefore I regard it as absolutely immoral to use it under any circumstances whatever; that is my view.

8737. You would let the child die?—I should.

8738. I only wanted your answer?—May I point out that that opinion was shared by Robert Browning, the poet—he distinctly expressed it—and it is shared by Bishop Moule. Bishop Moule says: "I cordially echo the words used by the late Dean Close, of Carlisle, that he would rather undergo suffering himself than have it inflicted on animals. Even if the suffering of one very dear to me could be alleviated by *the conscious torture* of dumb animals, I think I should have the courage to say that the animal was sacred to its Creator, and that not even to relieve my dear one should the unresisting animal suffer. Having said

this, I think I have gone as far as man can go." Those are the words of Bishop Moule, of Durham.

8739. Although the animal suffers very little, and the child suffers, from what one sees, an intensely painful death?—The question of how far the animal suffered is again a matter of opinion. One has heard dreadful things about animals that die in getting immunised.

8740. Exactly the same principle would apply to vaccination?—Yes; it is not so serious—not so terrible, to my mind, but I am an anti-vaccinator; all anti-vivisectors are not; but I cannot see how anybody can be an anti-vivisector without being an anti-vaccinator—that is logical.

8741. Now, I want to put this case to you, just to test it: We lose in India a great many lives from snake bites, as you know—20,000 lives a year. By experiments on animals lately, as we have heard in evidence, a new method of applying a chemical remedy has been discovered. Are we justified in applying that remedy now, although it was derived from experiments on animals?—Certainly, because it is not the product itself of vivisection.

8742. The experiments themselves were wrong, were they?—The thing itself has been misused, in my opinion. It should have been tried on animals or people who had been already bitten by snakes, by the act of Providence—by accident.

8743. Then take this case, as a matter of right and wrong. Here is a remedy, you do not know its effect; you believe it may be useful. Are you justified, when a man is dying from snake bite, in trying an experiment on him?—If it is for his own good, then it is noble, like the art of the surgeon; if you inflict pain for the good of the person. If you tell him you are running a risk, if you think the man is going to die without—if you say to him "We know of nothing else, would you like this experiment made?"; that is the proper person to make it on. If God sends me suffering it is for me to bear it and take all possible chances of recovery, but not in a panic to go and cause all sorts of wretched creatures to have it inflicted upon them that I may escape a little suffering and death, which must come some day.

8744. Do you think it is justifiable, not knowing whether it would be successful or not, to try it on man, rather than taking a certain number of animals, and finding out that it was a real remedy?—I was talking about the case of a man whose life was in danger.

8745. You have a list of remedies that you may apply. Are you justified in trying a new remedy and rejecting the old ones in order to find out whether the new remedy is a good one? There are several remedies for snake bite; a new one is suggested, are we justified in neglecting the old remedies and trying the new untried one for the first time on a human being?—Certainly not if the doctor thinks there is any chance with the old one; but when the doctor knows there is not, then let him make his trial if he thinks he has a more powerful remedy, if he can get the consent of the person. One of the things about inflicting experiments on animals is that they cannot speak, and do not know that it is being done. If suffering comes to anything naturally, then let us do all we lawfully can to relieve it; but do not let us take the creatures which enjoy their lives before God and inflict horrible diseases upon them.

8746. (*Mr. Tomkinson.*) I understand that you object *in toto* to the principle of vivisection of living animals?—I do.

8747. On the ground that pain must necessarily be inflicted thereby?—As I have said before, I am for the total abolition of pain. I object to making living miserable.

8748. In paragraph 12 of your *précis*, I understand, you say "That being so, while I might painlessly sacrifice the life of many animals to save one valuable human one, I would not have one mouse vivisected to save the greatest of human beings nor the life dearest to me"?—I added in my copy the word "painfully"—"painfully vivisected."

8749. You mean without anæsthetics?—Yes, and without being destroyed before it recovers. I say I am afraid that is impossible.

8750. You appear to have a great disbelief in the total invariable application of anæsthesia to these operations. You can hardly believe that in all cases, especially in operations, the anæsthesia can be complete?—That is a scientific question that I am not qualified to answer; but I think I may say this: that in questions of inoculation where the animals have to be watched for weeks sometimes and many days, of course it is impossible; and those are some of the most cruel of all probably. There are other cases in which we are told that the very administration of anæsthetics vitiates the experiment. And then there is a certificate on purpose to dispense with anæsthetics; and if there is a certificate which is used, we imagine that there are operations performed without anæsthetics; and we have evidence that it is so.

8751. We have had it stated to this Commission that rinderpest, which has been a tremendous scourge in South Africa and in India, has been practically guarded against by experiments upon a very few animals—by inoculating a healthy animal with the blood of an animal that has died of it, and obtaining from the blood of that animal experimented on a serum which has proved an effectual prophylactic against the scourge. Does that commend itself to you?—I do not think we have the slightest right to do that; it is against the principle I have enunciated several times. And I may just add that I happened to be at an anti-vivisection debate the other day, when that very point was mentioned, and there happened to be a South African lady sitting next to me, who challenged, from some statement she had lately had from South Africa, the statement that rinderpest has been combated. We are so accustomed to have all sorts of cures boomed; they all come with a great flourish of trumpets, and then they all pass away, like Koch's cure for consumption, and the rest.

8752. (*Chairman.*) But you would not say that when a physiologist or a well-known veterinary surgeon made a statement of that sort about the effect of antitoxin in South Africa, its value was very seriously deteriorated from because a South African lady contradicted it?—The real value, I should think, was that the process of time is beginning to show that he had made a mistake, if she was correct.

8753. Of course, he may have made a mistake, but it is not much evidence that he did?—I do not say so; as I say, I am not giving scientific evidence.

8754. (*Mr. Tomkinson.*) But surely, you would think it right to inquire how far that is a question of degree; how much suffering was caused to the animal from which the serum was obtained, and whether, by what may have been only inconvenience or a little pain and illness, the lives of thousands of that animal's fellow creatures were saved. You would surely take that into consideration, would you not?—Evidence of that sort, you know, first of all, is always very dubious; but leaving that quite alone, I say, no. You must have some guiding principle in life, and if my principle is right, then that act is wrong. May I just say that I have evidence of some dreadful operations which were performed by Professor Neisser?

8755. (*Chairman.*) That is getting into scientific questions, you know. I thought you rather refused to go into them?—It is a question of morality. He has made a statement on morality.

8756. It is a statement made by some foreign professor?—Professor Metchnikoff, Director of the Pasteur Institute, in his new book, "The New Hygiene"—it is a question of morality—says: "In questions of health morality should not attempt to lead hygiene, but should rather follow her."

8757. I think we have had that quoted to us before somewhere. I rather protest against the opinions of foreign physiologists, who are acting under totally different laws altogether from ours, on the question whether or not we ought to alter our laws. I do not care for Professor Metchnikoff's views about morals; his views on morals will not influence me any more than those of the man in the street?—But Professor Metchnikoff's statement is that morality is to be secondary to hygiene, and when he was over here an English gentleman got up and proposed a vote of thanks to him for his lecture, and yet he had made this quotation in support of the most horrible inoculations of women and children and monkeys with a terrible disease—syphilis.

8758. These are things which could not have been done in England?—But, at any rate, when these foreign men come over, we do not have instances of English

Rev. L. S. Lewis, M.A

29 May 1907.

physiologists repudiating what they do. On the contrary, they meet them with acclamation, and honour them in every possible way.

8759. I do not think we need keep you any longer?—I do not know whether I ought to say this. In my 13th paragraph I say: "The logical outcome of experiments on animals is experiments on man. The right to perform such has been claimed and carried out." I do not know whether I ought to substantiate that. I have got the materials here.

8760. I do not think that quoting a number of opinions of people to the same effect helps us; you are giving your evidence, but not the evidence of all these people?—I am referring to my paragraph 13.

8761. I think we have had that before. Probably the statements which you have are the same statements which we have had of certain physiologists to that effect, that some physiologists have made experiments and have actually carried them out on themselves?—But these are very different; these are experiments carried out in asylums and hospitals.

8762. In England?—In Germany and America, and some in this country.

8763. Were those in this country a breach of the law?—There you ask me a big question. In America, for instance——

8764. I do not think we can go into that?—Not to show the danger? As a clergyman, who has been giving my life up to the poor, I can assure you that I am very much affected indeed in my opposition to vivisection by the danger which besets them. If we are going to have experiments on animals, the time must come when, logically, they must be tried upon men, and I have here serious admissions, such as giving people epileptic fits and different things, which I consider are most certainly most dangerous.

8765. I do not think we can have all these views of foreign gentlemen.

(*Sir William Collins.*) I understood the witness to say that some were in this country.

(*Witness.*) I should like to have given the whole lot—Ringer's Handbook of Therapeutics, for instance, New York edition, pages 585-8, 590, 591, published by Wm. Wood and Co.

8766. (*Chairman.*) That seems to be an American work?—No, I believe—I am not quite sure of this statement—that after the anti-vivisectors made a great stir about it, an expurgated edition was issued, when some of the experiments were objected to because of the outcry, but Dr. Sidney Ringer, Professor of Therapeutics in University College, London, tried the poison with salicine, "Using healthy children for our experiments"; those are his own words. I can read the description, if you wish it.

8767. Were these experiments experiments which were likely to cause any serious illness?—I can read you what was said: "Poisoning with salicine. 'In conjunction with Mr. Bury, I have made some investigations concerning the action of salicine on the human body, using healthy children for our experiments, to whom we gave doses sufficient to produce toxic (poisonous) symptoms. Our first set of experiments were made on a lad of ten. . . . He was admitted with belladonna poisoning, but our observations were not commenced until some days after his complete recovery.'" I want to dwell upon that—"some days after his complete recovery." One would have thought that he ought to have been sent to his parents. Then, "Among the effects recorded during this experiment are 'severe frontal headache, so severe that the lad shut his eyes and buried his head in his arm'; 'became very dull and stupid, lying with his eyes closed'; 'complained of tingling like pins and needles'—and other symptoms indicating severe depression."

8768. Was this on children in a hospital?—You see it is on "healthy children." I believe in a hospital; but that is a point one could look up. The fact that patient I was speaking of as being "admitted" points to it.

8769. You do not know?—No. "In case II. the experiments were made on a lad who had recovered from pneumonia, 'his temperature having become normal ten days previously.'" After he had this drug, the symptoms included "vomiting, dulness, deafness, laboured breathing, spasmodic movements, and quickened respiration and pulse." The report concludes with these words: "We must confess we felt a little relief when the toxic (poisonous) symptoms, which became far more marked than we had expected, abated." That is one example.

8770. (*Colonel Lockwood.*) What is the date of that?—Sidney Ringer's book, about 1883, I should think.

8771. (*Sir William Church.*) You must mention, if you please, that it was the New York edition?—I have mentioned that.

8772. Then I ask what is the date of this New York edition?—That can be ascertained.

8773. But Dr. Sidney Ringer's original work was long ago, before the Act?—Then there are some other cases I can bring forward.

8774. I mean, have these cases been added in the American edition?—I cannot say. I said that I could not be quite sure of that point; I said so before I read it.

8775. (*Chairman.*) The date being 1883, what Sir William Church suggests is that Dr. Ringer, in his original book, gave an account of various experiments which did not include some of these. I understand that the New York contained something more than the English edition.

(*Sir William Church.*) I thought it might be so.

(*Witness.*) What I have gathered some time ago, but how far it is correct I do not know, is that there was a considerable outcry at the time, and the next edition of the book had some of these cases not in it. There is another case which was reported in the "British Medical Journal" of January 7th, 1882, page 5. This was a report of a lecture by Jonathan Hutchinson, F.R.C.S., Senior Surgeon of the London Hospital, Consulting Surgeon to the Moorfields Ophthalmic Hospital, Professor of Surgery and Pathology in the Royal College of Surgeons, and that was the case of a man kept in a shocking state of eruption—to use the words of Jonathan Hutchinson, "he was in a miserable condition from pain and irritation." The man was kept purposely uncured for a few days in order that the students might see that the disease would not cure itself. Then afterwards, to use Jonathan Hutchinson's words, he waved the magician's wand and the man was cured. I say that such a thing is unjustifiable, that a man should be kept in a miserable condition from pain and irritation. The eruption had been out about ten days, and "affected the mucous membrane of his mouth as well as the skin." I am quoting the exact words. "You may remember that we kept him in bed for a few days before we used the magician's wand, in order that all might see that there was no natural tendency to amelioration. More *bullæ* came out." He mentions that the limbs, head, and other most sensitive spots were so covered with *bullæ* that there was nowhere a space as large as the palm free from them.

8776. (*Chairman.*) I do not think we can follow these out at length. We should all agree, I think, that to experiment upon children in a hospital, not with a view to curing them of the complaint that they have, but with a view to experiment upon them for other purposes to a degree that would inflict pain and possibly risk upon them, would be absolutely wrong, and not only wrong in itself, but most prejudicial to the interests of all hospitals, and it would also be a legal offence to do it. I think having stated what you have done is enough to show that if that is an accurate statement in that New York edition of what Dr. Ringer did on that occasion, it was a thing which most people would entirely disapprove of?—I have two very strong cases in England, one, the giving of epileptic fits, which is mentioned without any reprobation in the Gulstonian Lectures by Dr. Gowers.

8777. If these were cases of a breach of the law relating to vivisection the evidence would be most germane, but as it is they only indirectly come in, and therefore, I think, if we have that general statement and one or two instances to illustrate what you mean, that is all you can do?—May I give a case here of a man who after experimenting on cats, the first of which died in 20 minutes and the second in 33 minutes, and other animals, goes on to say, "We have made some observations clinically. To 18 adults, 14 men and 4 women, we ordered 10 grains of the pure nitrite of sodium"?

8778. Who made the experiment, and where?—This again is a report by Dr. Ringer and Dr. Murrill in the "Lancet" of November the 3rd, 1883. After trying it

on the cats, the first of which died in 20 minutes and the second in 33 minutes, they then turned round and tried these experiments on human beings, and here are the most painful results to read of what the people came back and said who suffered from an experiment which was the direct result of vivisection, apparently.

8779. I am afraid that these cases cannot be gone into at this length. I understand that your general principle is that vivisection might lead up to experiments on mankind. We have already had a great many of these cases introduced on statements made in papers, and when we have come to have the actual persons before us who were present to tell us what really took place, the effect of the whole account has given quite a different complexion to the particular passages quoted, and as this is not germane to vivisection, but is only being used as an illustration of what experiments upon animals might lead to, I think we cannot have it in detail, because we cannot have it in such a shape as would involve our having to investigate all these cases ourselves?—Then, my Lord, may I end with this. I have said, and I have tried to establish it, that I am afraid we have grave ground to fear that vivisection on animals will naturally lead to experiments on patients. May I conclude with reading the opinions—it is very short—of important people which support that view, for instance, Lecky.

8780. I really think that reading the opinions of a number of people, or saying I have got a number of opinions or letters written to me by people who agree with me, is a thing that we cannot have. We cannot investigate all their opinions?—But these are public statements in public books. Lecky, the great historian, in his History of European Morals, says "It is abundantly evident"——

8781. I see, Mr. Lewis, you do not take a hint from me. I think we must make an end of these quotations on a subject which is not really before us?—It is very hard to give moral evidence without giving quotations to support it.

Rev. L. S Lewis, M.A. 29 May 1907.

8782. It has little or nothing to do with our Inquiry?—Dr. Johnson warned us that it would lead to this sort of thing, and Lecky and some of the great thinkers of the world tell us that it is one of the great dangers of vivisection that a man who gets callous to pain, and does not inflict it for the good of the sufferer, will not be over particular when he gets straight from the vivisectional laboratory to the bedside of a hospital patient. That is what I have tried to explain.

8783. (*Sir John McFadyean.*) Might I ask one question with regard to this new evidence? You state that the logical outcome of experiments on animals is experiments on man. Is that true, just in the same sense as the logical outcome of running horses in cabs would be to run men in cabs?—Not in the slightest degree. I cannot see the logic of the second proposition. I can see the logic of the first.

8784. It is because I do not see the logic in the first one that I asked you to show me the defect in the logic in the second one?—Is it not plain that the vivisection of animals is performed for the sake of mankind, to cure the diseases of mankind?

8785. That is so?—Very well, then; that being so, sooner or later those experiments must be made upon man. It is very difficult, of course, to argue from an animal to a man; for instance, a pigeon, I believe, can take enough opium to kill about 80 or 90 people; therefore, considering that the time must come when experiments are made on man, those experiments will be made by a man who has deadened his feelings if he has been a cruel vivisector, or has not cared what pain he has inflicted upon the animals, so that he may attain his end; and I may say that the danger to patients, especially to the poorer patients, and to the community, is enormous, when they are in the hands of a man who has deadened himself in that manner.

Miss A. L. Woodward, called in; and Examined.

8786. (*Chairman.*) You also appear as a witness on behalf of the Church Anti-Vivisection League?—That is so.

Miss A. L. Woodward

8787. Of which you are Secretary, I think?—I am one of the Assistant Secretaries. I am the Acting Secretary, in fact.

8788. You were in the room when I explained to Mr. Lewis that we wished to take the ethical question somewhat more shortly than we have done with some of the previous witnesses, who have gone into it at great length, and perhaps you will bear that in mind?—Yes, I do not want to dwell very much on the ethical side. My evidence is rather a statement of matters of fact, which I have tried to arrange as briefly as I can, so as to take up as little time of the Commission as possible.

8789. You have sent us in a *précis*, I see, and the first thing you desire to give us is a statement showing that illegal vivisection has been practised in England?—The special point that I desire to bring before the Commission is the fact that the absence of convictions is no proof that the law has not been broken, and, further, that the Act has been so administered as to make such convictions a matter of practical impossibility. Thirdly, I would point out that a former witness was mistaken in saying that no complaints have been made of unlicensed vivisection, because such complaints have been made; and, moreover, that, so far from complaints of vivisection having been vague and general, and "nothing that one can lay hold of," as stated by another witness, they have, in some cases at any rate, been most clear and defined and circumstantial. The case which I would especially emphasise in regard to that, which is mentioned in the second paragraph of my *précis*, occurred in connection with a meeting of the Church Anti-Vivisection League in the Technical College at Bradford on September the 30th, 1898. The meeting was a somewhat rowdy one. I am now going to quote from "The Standard" of the next morning, which said that the meeting was "completely taken possession of" by our opponents ("The Standard" is not an anti-vivisection organ, as you know), "who set aside all ordinary rules generally governing the conduct of public gatherings." I am merely giving you an idea of the state of the meeting.

8790. What you are coming to is to show that Dr. Hime, of Bradford, had performed operations without a licence?—Yes, I am coming to that as rapidly as possible. The meeting was packed with medical students, and we had an instance in the Portman Rooms the other day of what that causes. There were also 26 doctors present, a whip having been sent round to over a hundred doctors in Bradford and Leeds. Having given you an idea of the state of things which accounts for what was said, I will suppress my own account of it and pass on to the statements of three persons who were present which were sent in to the Home Office.

8791. And Dr. Hime was present?—Yes.

8792. (*Sir Mackenzie Chalmers.*) Were you present yourself?—Yes. If these statements are not sufficient I can answer any further questions, but I hope they will sufficiently explain the matter. The first statement is by the Reverend Conrad Noel. These were properly attested statements, of which the originals, I suppose, remain at the Home Office. "Dr. Kerr, a Bradford doctor, arguing against the proposal that we should work for the total abolition of vivisection, *i.e.*, of all licences granted to vivisectors, as it would only result in illegal experiments being made, stated that such (illegal unlicensed) experiments were already being performed by his fellow doctors in Bradford. He further said that the reason for these unlicensed experiments being performed was that it was necessary in the cause of science that such experiments should be made, but that Dr. Hime, of Horton Road, Bradford, was the only experimenter who carried on such researches under the necessary licence. He alone held the licence. The Secretary of the Church Anti-Vivisection League handed him the Government returns, which made no mention of any licence held by Dr. Hime; and Dr. Hime, who was himself present, rose, and admitted that it was a mistake for Dr. Kerr to have said that he held a licence. Dr. Hime did not attempt to deny that he carried on experiments. I drew attention to these points in a letter to the 'Bradford Observer,' appearing on the following Tuesday, concluding by saying: 'Surely some explanation should be forthcoming from the doctors!' To the best of my knowledge no answer has been given by them excepting that Dr. Kerr at once wrote me a postcard, marked private, the contents of which I suppose I should not divulge, but which I may at least say does not in the slightest degree contradict his statement as to the illegalities being practised, but rather confirms these statements.—(Signed) Conrad Noel, November 29th, 1898, 279, Tamworth Road, Newcastle-on-Tyne, Curate of St. Philip's, Newcastle-on-Tyne," one of the

Miss A. L. Woodward.

29 May 1907.

speakers at the meeting. He adds in a postscript: "The above is drawn from notes made at the time compared with newspaper reports of the following morning."

8793. Is there any evidence that Dr. Hime, while he held no licence from the Home Office, did perform operations except the fact that you state that he did not state that he did not do it?—If you would kindly allow me to read the statement of the second witness it will perhaps make it clear to you. If not, I can answer any questions then.

8794. You say the second witness. You are the witness at present. I am asking of your knowledge, have you anything in your knowledge to show that, because if you say that a doctor performed operations contrary to the Act without a licence we ought to have evidence of that?—He made no attempt whatever to deny it. At the meeting I told him the matter would go to the Home Secretary. The second person who makes a statement goes a little further than that.

8795. Was the person present who makes the statement?—Yes. Dr. Hime throughout never attempted to deny it. There was a good deal of correspondence in the Bradford papers, and so on. He had every opportunity of denying it if he was flustered at the time.

8796. The charge was put in quite a different way—that he had no licence. But you say that you have a second statement?—I have it here.

8797. But in order to show that Dr. Hime operated without a licence, if that is what is intended to be proved ——?—I think I have already stated that the second statement is rather more emphatic on that point and will give you a little more information as to what he did say.

8798. But if you will allow me also to put what I have to say, it is that a statement made by somebody to the effect that Dr. Hime operated without a licence is not a thing that we can have except from the witness who makes it?—I am not asking you, who are not like the Home Secretary the judge of this case, whether you think it proved or not that Dr. Hime did commit an illegal vivisection, my point is that complaints of illegal vivisection were brought to the Home Office and disregarded by them; it is the second point. Whether in your own mind you believe Dr. Kerr to have spoken the truth or falsehood is another question altogether.

8799. Nobody suggests falsehood in the sense in which you suggest it, but you are going to make a complaint of the Home Office?—I am coming to that.

8800. Was this statement which you are about to read sent to the Home Office?—Yes. This is from Mrs. Ring: "I was present at the meeting of the Church Anti-Vivisection Society held in Bradford during the Church Congress Week this year, and heard a Bradford doctor (whose name I do not know) state that there were 'hundreds of vivisections done in Bradford'; he also said that Dr. Hime was the only licensed vivisector. Dr. Hime did not contradict this, but said he had 'performed hundreds of vivisections, and should continue to do so.'" That is the point, that Dr. Hime according to this statement distinctly admitted it.

8801. That is the statement of some person which was sent in to the Home Office?—Yes. "Then later on, when the Secretary of the Anti-Vivisection Society produced a list of licensed vivisectors, and asked to be told under what licence he did them, as his name was not down—he called out that it was a 'mistake,' he was not licensed.—(Signed) G. A. M. Ring, Rawmarsh Rectory, Rotherham, November 30th, 1898." And this is the third brief statement.

8802. Was it sent in to the Home Office?—Yes; they were all sent in. "I also was present at the Bradford meeting, and can testify to the accuracy of the above statement.—(Signed) T. P. Ring, Rector of Rawmarsh." Therefore two people, if you lay stress upon that point, speak to the fact of Dr. Hime having said that. My own written statement had been previously sent in.

8803. What happened upon that?—A good deal of correspondence with the Home Office, and this is the final letter of the 11th January, which I will with your permission read.

8804. Thank you?—"Whitehall, 11th January, 1899. Madam,—With reference to your letters of the 19th October and 1st December, 1898, drawing attention to a supposed breach of the Act 39 and 40 Vic., cap. 77, by Dr. Hime, of Bradford, I am directed by the Secretary of State to inform you that he has caused inquiry to be made, but that no case of illegal experiments on living animals has been discovered or brought to his knowledge by Dr. Kerr or by any other person.—I am, Madam, your obedient servant, (Signed) Henry Cunynghame." I venture to say, my Lord, that to require Dr. Kerr himself to come and give this evidence was a very extraordinary excuse to make. It was strange enough that in a moment of excitement he should have betrayed his friend, but even a person of most ordinary intelligence would see that it is preposterously absurd to ask that he should be expected to come in cold blood and repeat that action without any motive moreover for doing so. It seem to me, with all due respect to the Home Office, that it would be very much as if the police should decline to act in a case of alleged burglary until one of the burglars was kind enough to call at the police station and give evidence of the details of what had been committed. However, the matter was not allowed to rest there. I wrote again, and very strongly, to the Home Office, and said that questions would be asked in Parliament. I have here a copy of extract from a proof of the "Parliamentary Debates" of the 2nd March, 1899, which with your permission I will read:—"*Mr. MacNeill* (Donegal, S.): I beg to ask the Secretary of State for the Home Department whether he is aware that at an anti-vivisection meeting held at Bradford on the 30th September last, Dr. Kerr, speaking against the proposed withdrawal of licences granted to vivisectors, said the effect of the proposed step would be to increase the number of illegal experiments on the bodies of living animals, and that such experiments were performed by many of his fellow doctors at Bradford, as it was necessary in the cause of science that such experiments should be made; whether he is aware that Dr. Kerr stated that Dr. Hines"—(it should be Dr. Hime)—"of Horton Road, Bradford, was the only vivisector in Bradford who carried out experiments in vivisection under the licence required by law, and that Dr. Hines, who was present, stated that he had performed hundreds of vivisections and should continue to do so; whether he is aware that the Secretary of the Anti-Vivisection Society produced a list of licensed vivisectors, on which the name of Dr. Hines did not appear; and whether, in view of these facts, he intends to take any, and what, steps for the enforcement of the law against the practice of unlicensed vivisection." Then Mr. Jesse Collings replied: "The Secretary of State for the Home Department believes that at a somewhat excited meeting in Bradford on the date mentioned statements to the effect suggested were made. His attention was drawn to the matter at the time, and he caused inquiry to be made, but could not elicit any clear statement of what was actually alleged, nor any evidence of illegal vivisection being performed by Dr. Hime—not Hines. There are, therefore, no steps which he can take in the matter. I may add that it should be remembered that performing upon an animal an experiment calculated to give pain without a licence is an ordinary criminal offence which any person may prosecute." The important part of that answer appears to me to be the admission that the Secretary of State believed that statements to the effect suggested by Mr. Swift MacNeill were made.

8805. At the meeting?—Yes, at the meeting. Therefore he absolutely disregarded the testimony of four people, two of them clergymen and presumably men of education and accuracy.

8806. Do you know whether the Secretary of State applied to Dr. Hime for an explanation?—I have no certain knowledge. I heard so, but that is not a matter that I could prove.

8807. Do you know whether any other evidence except statements by Dr. Kerr and the statement of Dr. Hime at the meeting were before him?—That I could not say.

8808. At any rate he said that he had investigated the matter and came to that conclusion?—Yes.

8809. (*Colonel Lockwood.*) Did you hear Dr. Hime make these statements?—That is why I wanted to lay stress upon the rowdy character of the meeting. There was a great deal of noise going on, and it was difficult to hear on account of the students with their usual proceedings. I could not swear from my own knowledge that he said that he would continue to perform them. There is the testimony of two people to it that he said he had performed hundreds and would continue to do so.

8810. (*Dr. Wilson.*) Do you know whether any inquiry was made as to whether this was in connection with the production of vaccine lymph?—We had no opportunity

of making a legal inquiry. It is useless to tell you the reports in Bradford. I heard reports of very different things about dogs, but being merely report it is not a thing that I wish to bring before the Commission.

8811. (*Chairman.*) The fact that you desired to bring before us was the conduct of the Home Office?—First of all, the mistake in saying that cases of alleged unlicensed vivisection were not complained of; and, secondly, as to the past administration of the Act. The next case I have is not so flagrant an instance, but it still does prove again that complaints were brought. This has reference to a Lecture on Physiology by Dr. Langdon-Down in University Hall, Gordon Square, on December 9th of the same year. A lady who was present at it wrote to us complaining that he had vivisected a frog (I cannot say that personally) at a meeting in connection with the Child Study Association, a society which had a licensed vivisector for the president of one of its principal branches, and as the hall in Gordon Square was not registered for vivisection we in reply advised this lady to communicate with the Home Office. She did so, and this was the reply received: — "Whitehall, 28th January, 1899.—Madam,—In reply to your letter of the 14th instant drawing attention to demonstrations given by Dr. Langdon-Down in the course of a lecture on 'Physiology and its relation to Child Study and Education,' I am directed by the Secretary of State to say that he has made inquiry and is informed that the demonstrations you refer to were not 'experiments calculated to give pain' within the prohibition of Sec. 6 of the Cruelty to Animals Act, 1876.—I am, Madam, your obedient servant, (Signed) Charles S. Murdoch."

8812. What is your complaint against the Home Office there? Supposing what Mr. Murdoch says there were true, that would be an answer, of course?—I make no complaint against the Home Office there.

8813. (*Sir Mackenzie Chalmers.*) Then what is the point of the evidence?—To show that it is quite a mistake to say that complaints of illegal vivisection were not made. I give a second instance of that.

8814. You mean that a false complaint was made in that case?—No, I do not. I think the letter itself is an admission that a frog had been vivisected there.

8815. (*Chairman.*) A complaint was made about something which, on investigation, the Home Secretary satisfied himself was not a breach of the Act?—He satisfied himself, or, rather, he believed the report of the gentleman, that there had not been sufficient pain caused.

8816. He satisfied himself on such materials as he had before him that there had not been a breach of the law?—If you ask my opinion about the Home Secretary, I would say that he is very easily satisfied, but I do not wish to lay stress upon that. My only point there is that a complaint was made.

8817. (*Colonel Lockwood.*) Two complaints?—Yes. That was with regard to the Child Study Association. There is not the same volume of evidence there, and personally I do not see that the Home Secretary was to blame for not acting upon it; but it proves that Mr. Byrne was mistaken in saying that complaints are not brought.

8818. Could you give us the reference to Mr. Byrne's evidence?—It is at Question 147.

8819. (*Dr. Wilson.*) But are you sure that the frog was vivisected, because the web of a frog is often used to illustrate a lecture without wounding the frog at all?—I am quite sure, from what people said who were there. I was not present myself, as I was on the other occasion.

8820. (*Chairman.*) Your evidence has been addressed to showing that Mr. Byrne's answer to Question 147, in which he says that any alleged breach of the Act has always been brought before the Home Office by the operator himself, is not correct, and that complaints have been made from outsiders?—Yes, exactly; and, furthermore, as our League is only one of many anti-vivisection societies, it is so extremely improbable that every case would be brought before us that I think you may reasonably suppose that these are but typical cases of those occurring from time to time. Just as an instance of that, I may mention the well-known case of unlicensed vivisection at Burroughs and Wellcome's Laboratory at Herne Hill, which is so well known to the public that I do not wish to take up your time by going into it in detail. In that case the Home Office, instead of punishing the breach of the law, gave them a licence afterwards.

8821. Mr. Byrne, of course, clearly made that answer, and those letters which you have read show that it is not quite accurate—at least, they seem to show that; but, of course, they both come to nothing in the opinion of the Home Secretary?—I am afraid that accusations always have hitherto come to nothing in the opinion of the Home Office. That is the unsatisfactory state of the administration of the law.

8822. (*Colonel Lockwood.*) Still complaint was made all the same?—Yes, that is my chief point.

8823. I was going to ask, whether it came to nothing or not, complaint was actually made and lodged with the Home Office and answered by them?—Yes, that is my point.

8824. Therefore, that answer of Mr. Byrne's is incorrect?—With regard to complaints being vague and general, and "nothing one could lay hold of," I have read with surprise that those statements emanated from Professor Thane. I allude especially to his answers to Questions 1284 and 1285, in the latter of which he stated that he could not specify anything as to whether such complaints were general objections as to a matter of principle or to any nuisance. The reason for my surprise is that I am informed that Professor Thane has for years held the position of Professor of Anatomy at University College, and it is very difficult, therefore, to understand how he could have failed to be cognisant of a very extensively signed memorial presented in the autumn of 1903 to the head of the college, Mr. Gregory Foster, by the great majority of female students in the Slade School of Art, as to the very great hindrance to their studies caused by the terrible cries of the vivisected animals. Anyone who knows the dread which any body of young people have of approaching the authorities of their college will understand that things must have been very bad indeed before so marked a step was taken. My special point, however, is that if Professor Thane, the Inspector under the Act, had really wished for information, he had every opportunity of obtaining any amount of information at first hand, because the names of the signatories were all open to him. Our League, as is expressed in its constitution and as one member of the Commission has remarked it to-day, bases its opposition to vivisection solely on moral and religious grounds, and that being the case, we have made a special feature of our warfare against the practice that it is a system of corruption of youth. In connection with that, I may mention that a very short time ago I was interviewing a young man who, at the age of 14, was employed in Professor Victor Horsley's laboratory. He threw up his situation at the end of three months, saying to me that he felt that if he continued it (I am using his exact words, and you must please excuse the English) "he would become one of the most cruel-hearted devils alive." I think if the Commissioners could have heard the cry wrung from that young soul they could not have helped asking themselves whether, even if the claims made for this pseudo science to utility could be made good, the game is worth the candle. Again, in University College a few years ago, the dogs for vivisection were bought at a shilling apiece from the caterer's boy. Now, I hold that it would be an insult to the intelligence of the purchasers to suppose that they did not perfectly well know that such animals must have been stolen. I do not know the present fate of that lad, but if he has become a thief, and if he is practising in his manhood what he learned in his boyhood at University College (and there was such a case, if you will allow me just for one moment to mention a case which is not English, not so long ago in the police courts in America, where the excuse made by the criminal was that he had been taught to steal animals when a boy for a similar laboratory), if that young man has had a similar fate, I say boldly that before God and man the authorities of that college are responsible for his moral ruin and for all the evils brought by the habitual criminal upon the community at large—as responsible as if they themselves had practised the profession of Fagin. I have only one last point to bring forward as to the corruption of youth. I hold in my hand a book which was used by the London School Board for pupil teachers. It took our League a hard fight of six years to get it properly expurgated. The book is by their special science teacher, William Furneaux. He there recommends those young people in a very atrocious ex-

Miss A. L. Woodward.

May 1907.

periment to irritate the exposed nerves of the victim, saying that when they do that at certain points of the experiment the animal will show signs of most acute pain, and in another case he says of intense pain.

8825. (*Chairman.*) Are you quoting that from his writings?—Yes, I have the book here and the page marked.

8826. Will you just state the page?—It is page 189 of "Animal Physiology," by William Furneaux, Fourth Edition, 1892—the special science teacher of the London School Board. I think, my Lord, those words of his form a very curious commentary on the assertions as to the painlessness of vivisection so freely made to this Commission. I have listened, of course, to what has been said this morning, and I venture to think that they supply a very good answer to the insinuation made that we anti-vivisectors ought to turn our special attention towards other forms of cruelty. I think they give us a right to say that beyond all other forms vivisection is a danger to the community and a foe to humanity, and that therefore our very special attention should be directed against it. That is all my evidence in chief. I want, if I am allowed, to add one word about the work of our League on one small point. It has been stated here that the "Shambles of Science" has been withdrawn, and it has been stated that it has not been withdrawn. Our League is in a position to give a little information upon that point.

8827. I think we quite understand the position from Miss Hageby?—I will not keep you one minute. Possibly Miss Lind-af-Hageby did not know this. Every year we have offered that first edition publicly for sale to the public at our stall at the Church Congress, and we should not have done that if we had not been very sure of what the Lord Chief Justice said—that is all.

8828. (*Sir Mackenzie Chalmers.*) I want to ask you about Dr. Hime's experiments. What experiments did he perform?—That I cannot tell you; they were not mentioned.

8829. But really, when you accuse him here of having performed unlicensed experiments, surely you must have inquired what they were?—No, I did not; it was not my business. I brought it before the Home Secretary, whose business I supposed it was. Of course, Dr. Hime might naturally have said that it was a piece of impertinence if I had asked him. He was not bound to give me information; he was bound to give it to the Home Secretary.

8830. Why was he bound to give it to the Home Secretary. He was not a licensee?—Because the Home Secretary is the person whose business it is to ask questions.

8831. I beg your pardon. An unlicensed person who performs experiments is like any other person who commits a criminal offence. Will you show me anywhere in the Act where it is the duty of the Home Secretary?—Then if it is not, it only goes to show how unsatisfactory the present Act is. But the Home Secretary himself did not make that excuse for not acting.

8832. He made inquiry?—Yes, he accepted his responsibility. A good deal of correspondence went on.

8833. He may have tried to satisfy himself and to satisfy you, because, as it turned out, there was nothing in it. But you made no inquiry yourself, and even your society made no inquiry, as to whether any experiments had been performed?—We were not the people to do that, but we did do this, and I think we were about the only people to do it. Mr. Noel and I went before a magistrate the next morning and asked if we could have a search warrant to search Dr. Hime's house. That is provided for in the Act, and we were on the point of getting it until another magistrate came in who was more hostile to us and refused it.

8834. Did you swear an information?—No, because we had not come to that point when the other magistrate came in.

8835. Before you can get a warrant you have to swear an information, have you not?—Yes, we had a copy of the Act with us.

8836. At any rate, you applied for a warrant and the magistrates refused it?—Yes.

8837. Are you aware that if an offence is committed by an unlicensed person anybody can prosecute?—I am aware that that is the theory of the law, but you must perfectly well know that as long as vivisection is performed in secret no private person can prosecute; it is a practical impossibility.

8838. Then how can you say that the Home Secretary is in a better position than any other person?—I do not think it is my business to answer that. I must respectfully ask that the questions are such as are reasonable, and can be replied to. I am not here to answer on a legal point. I am only here to speak to facts. That is a question to be asked of a barrister.

8839. Then I will put it in this way. I am not asking a legal question, I am asking a matter of common sense. If an offence is committed in secret how is the Home Secretary in a better position to find it out than any private person?—He is in a better position to find it out because he is more likely to have his questions answered, but he cannot always find it out either. It is precisely one of the strong arguments against allowing vivisection that it is incapable of regulation.

8840. We are discussing now vivisection by an unlicensed person; that is illegal at present. How would you make it better by making vivisection illegal? Would it not go on in secret?—Some would, but, of course, very much less, because people would be afraid of its being found out, and, moreover, all the corruption of students would be done away with then. I think the system would mostly die out. Take a case that the law does forbid now. The law forbids murder. Unfortunately murder is committed, but if the law legalised murder I think you would find that there would be a great many more murders.

8841. Coming back to Dr. Hime, you say that you do not know what experiments he performed or whether he performed any experiments?—No, I have no knowledge. It is no use to repeat reports that went on in Bradford.

8842. You have told us what was said by the Home Secretary; you have not told us what was said by Dr. Hime himself. You know that he wrote to the Bradford newspapers?—Yes.

8843. Why have you not given us his letter in which he repudiated the statement altogether?—I have the letter here.

8844. Will you kindly read it?—I said to the Chairman that I wanted to be as brief as possible.

8845. In being brief you omitted to read Dr. Hime's letter in which he contradicted all the facts?—I do not admit that he contradicted all the facts. If I read his letter may I read my reply in the Bradford paper? It is only fair.

8846. (*Chairman.*) Is this a letter from Dr. Hime to you?—No, it is a letter to the paper. We both wrote to the paper. This is his letter: "Sir,—I ask your favour to permit me to reply to a statement under the above heading, which appeared in the 'Observer' of March 2nd and again on March 3rd. On March 2nd it was stated that Mr. MacNeill, M.P., was to ask the Home Secretary in the House of Commons, *inter alia*, if he was aware that I had stated at a public meeting that I had 'performed hundreds of vivisections, and should continue to do so,' though I had no licence for experiments. I may say that Mr. MacNeill's question, as printed in the notice paper of the House of Commons, referred to 'Dr. Hine's,' which is transformed in your paper into 'Hine.' If Mr. MacNeill intended the above statement to refer to me, I repudiate it, and deny that there is one particle of truth in it. It seems to me a gross abuse of the privileges of a member of the House of Commons that, while shielding himself under the form of a question to a Minister, a member may make an utterly unfounded charge against a person, who, knowing nothing of his intention, cannot take the necessary steps to have the falsehood killed when and where it is uttered. Mr. MacNeill's proceeding is not one whit justified by his statement being founded on the untrue remarks of a third party. No fair-minded person will approve the conduct of the Minister who, before replying to such a question, involving slander of an absent person, who knows nothing of the liberties being taken with his name in the House of Commons, failed to communicate with the person referred to in the offensive question.—I am, etc., THOS. WHITESIDE HIME." This was my letter:—"Sir,—If the subject were less sad Dr. Hime's assumption of injured innocence in his letter to you would be amusing. He must be aware that newspaper paragraphs are not always absolutely accurate. Has he forgotten that one, if not more, of the Brad-

ford papers announced, on Mrs. Hime's authority, that on the night of the historic meeting he was ill in bed, and had lost his voice, although all of us who were at that meeting can testify to his being in very good voice when he appeared at the head of the rioters? I make no doubt that what Mr. Swift MacNeill really said was that Dr. Kerr had stated that Dr. Hime was performing a great many visisections ('a lot of vivisections' was Dr. Kerr's actual expression), and that when it was proved he held no licence, Dr. Hime made no attempt to deny the vivisections, even when informed that the matter would be brought before the Home Secretary. I do not see myself that Dr. Hime gains much by the publication of the correct version, and, if he will take the advice of an opponent, I should strongly counsel him not to perform illegal vivisections in future. The Home Office has shielded him this time in defiance of a large amount of evidence, the Home Secretary having been supplied with the written statements of four persons present. But should Dr. Hime venture in the future to torture helpless and confiding creatures, it is possible that he has not yet heard the last word as to this matter.—I am, etc., A. L. WOODWARD." The first part shows us, I am afraid, that reliance is not always to be placed on the word of that gentleman—I refer to his saying that he was laid up with a sore throat.

8847. (*Sir Mackenzie Chalmers.*) Did he say so?—The letter, on the authority of Mrs. Hime in one of the Bradford papers, said so. Again, if it was not true it is peculiar that he did not deny these various statements publicly made. Still, that does not affect my main point, which is that complaint was made and that every obstacle was thrown in the way by the Home Office.

8848. Did you produce any evidence of these experiments to the Home Office?—I have told you precisely what we did.

8849. Will you answer my question, please; did you produce any evidence of these experiments to the Home Office?—Beyond what was said at the meeting, certainly not.

8850. (*Chairman.*) I did practically ask that question, and I understood Miss Woodward to say that the evidence produced was the statements made by these three gentlemen about what took place at the meeting. (*To the Witness.*) You did not produce any evidence from Dr. Hime's laboratory to show it?—We tried to get that evidence, but the magistrate would not allow us to go in, you see.

8851. (*Sir Mackenzie Chalmers.*) You were as unsuccessful with the magistrate as you were with the Home Office?—Precisely, as everyone will be while the law remains what it is now.

8852. That was in 1899. Then you referred to another case in 1899; what was the experiment in that case; at any rate, you made an allegation in the case of an experiment at a lecture?—One of the persons present did.

8853. Will you tell me what the experiment was?—No, I cannot tell you the details of it; I was not present there and I am not a physiological person.

8854. Then why do you bring it before us now?—To show the fact that complaints were made from time to time.

8855. Founded or unfounded?—That I leave to the Commissioners to judge for themselves. I am not the jury in this case.

8856. Now we will go on to Dr. Langdon-Down. You say there was a memorial from the students of the Slade School of Art?—Yes.

8857. You have not got a copy of it, have you?—No, I never have had a copy. I have been told of it by several people at first hand.

8858. How far is the art school from the laboratory?—The women's part is very much nearer than the men's, which accounts for its being female students chiefly. I have been told by people who have been there for years that the male students cannot hear the cries of the animals except in one or two rooms, in one of which they study the antique, as my informant called it.

8859. What I want to get at is this. You talk of the cries of vivisected animals; what is your authority for saying that these were the cries of vivisected animals?—It is the students who say they are the cries of the vivisected animals.

8860. What is the use of your coming here to tell us what somebody else says?—Because my point was how very easy it would have been for the Inspector to have information if he had really wished for it. Other people have told me the same. I can mention the names of other people who have also heard those cries.

8861. You heard cries from an animal, but I want to know why you think they were the cries of a vivisected animal?—The sounds came from the laboratory, and they were the cries of animals apparently in terrible pain. No other animals were likely to be in great pain there except vivisected ones, and if I heard horses make a sound in a stable I should naturally infer that they were the sounds of the horses kept in that stable, if I knew that there was a stable there.

8862. You know nothing about it yourself. I will take that?—I never said that I did.

8863. Can you give us any case since 1899?—As I have been asked about University College, if I might mention for one moment quite other work, in interrogating candidates for the Borough Council last November, two of their own accord told me that they were strong anti-vivisectionists, because of the cruelties they witnessed there.

8864. (*Chairman.*) We cannot have that. If these gentlemen connected with the Borough Council think the laboratory is badly conducted they can come and say so?—You can have them before you. I have no doubt they will be willing to come.

8865. We have had many witnesses on both sides?—I say it in answer to the Commissioner, who rather insinuated that there is not sufficient evidence. He can have plenty more at first hand if he wishes it.

(*Sir Mackenzie Chalmers.*) First-hand evidence here is the only evidence that is of use to us.

8866. (*Sir William Collins.*) Did I rightly understand, from the letter that you read of Dr. Hime to the "Bradford Observer," that he complained that he had not been communicated with by the Home Office in regard to what he called an offensive question?—I gather that, certainly.

8867. Then as regards the book that you quoted by Mr. Furneaux, did I correctly understand you to say that some change had been made as the result of a representation?—Yes, twice.

8868. What were those changes?—The first change was simply that he suppressed the words "intense pain" and "most acute pain." We, of course, were not satisfied with that as he described the same operations. We fought it at three elections, and at the last of those, which took place six years after our first fight, a majority of the Board were returned pledged to us, and asked us what we wished done as soon as they were elected. We suggested the entire alteration of that chapter, as with that exception, the book is an excellent manual on physiology.

8869. Did you gather that the passage in that book to which you take exception was an indication or intimation to students to practise that painful experiment, or was it a record of previous experiments which had been made?—I think if you read it yourself you will see that there is a decided suggestion that they should practise it. The Board themselves took it as such, because they first of all, so I was told by a member of the School Board, if I may repeat second-hand evidence, sent for some head teachers and told them they must take care that such experiments were not practised; so that evidently they recognised the danger of its being acted on.

8870. Is that manual still in use?—I am not quite sure.

8871. (*Dr. Gaskell.*) Was that a manual for children?—No, for pupil teachers. There have been some very extraordinary things in manuals for children too, but this was for pupil teachers. There was nothing so bad in the manuals for children.

8872. The animal experimented upon was a frog, I suppose?—I should think it was a monkey. That is rather insinuted, because the fingers were spoken of.

8873. Then am I to understand that your pupil teachers are so rich that they can afford monkeys to practise upon?—Will you allow me to say that I have no pupil teachers.

8874. The pupil teachers belonging to the Child Study Association, is it?—No, it was the pupil teachers of the London School Board.

Miss A. L. Woodward
29 May 1907.

8875. I thought you said Mr. William Furneaux?—He was their special science teacher. (*Handing the book to Dr. Gaskell.*) The passage as to the fingers is on the next page. That is in the experiments I described.

8876. Yes. I have looked at it, and I should have thought it was simply a statement of fact as to what happened when you stimulate the posterior root of the nerve, so that it could not have been intended really that they should carry out the experiment?—If we judge by the ordinary rules of English grammar it is the imperative mood that he uses—"irritate."

8877. It is a statement of what happens when you do irritate the posterior roots of the nerve?—Yes.

8878. Is it a recommendation to students to get a monkey and irritate the posterior roots of the nerve of a monkey?—If it is not an injunction to do that, then Mr. Furneaux' grammar is very much out, as he uses the imperative mood.

8879. It is "if"—it is not imperative?—No; pardon me, it is "irritate" in two cases—the imperative is clearly used.

8880. I can only see "if"?—I can show you where the imperative is used.

8881. In the case of Burroughs and Wellcome's do you understand that there is a difference between vivisections which are done for commercial purposes and those which are done for experiment?—I do indeed. I think they are far more dangerous when they are done for commercial purposes.

8882. You speak of Burroughs and Wellcome as being unlicensed vivisectors?—Yes.

8883. Is not that still going on now?—But they have had a licence given them; it was brought by the International Anti-Vivisection Council before the Home Secretary in the year 1900. He then asked the advice of the Colleges of Physicians and Surgeons, and both of them reported unfavourably to granting a licence to Burroughs and Wellcome; but when the doctors happened to be on the other side they were not attended to, and the place has been registered for vivisection ever since.

8884. But for a number of vivisections that are done in commercial schools you do not require a licence; is not that so?—It was held that Burroughs and Wellcome's vivisections did require a licence. I should not think they would be legal without, but there again I am not here to answer legal questions.

8885. You are not aware, apparently, that Dr. Hime is one of those who supply glycerised calf vaccine at the present time?—I was not aware of that fact.

8886. And it is taken up by the Local Government Board and supplied throughout the kingdom, so that Dr. Hime's experiment, this vivisection that you are speaking of, was mainly for the purpose of obtaining calf vaccine—you were not aware of that?—Pardon me, I do not think that he held any such appointment at that time. I have not followed his career very closely of late.

8887. But when he spoke of hundreds of experiments was not that for providing vaccine?—I cannot say what he meant, but I think it very unlikely, as I suppose no licence would be required for that.

8888. (*Sir John McFadyean.*) He never had an appointment; he did it in his private capacity. (*To the witness.*) He might do it in his private capacity, might he not?—That would be vaccination rather.

8889. No; the manufacture of vaccine can be carried on by a private person?—That would hardly be called vivisection, although it is so, we know.

8890. (*Dr. Gaskell.*) When Dr. Hime spoke of the number of vaccine experiments, and said that he was going to continue them, was not that simply in the preparation of calf vaccine?—It would be very peculiar if it were so.

8891. (*Chairman.*) Do you know whether it was so or not?—How can I know? I have told you exactly all I know.

8892. If you do not know anything about it you can say so to the Commissioners?—Exactly, I say so; then I only added in courtesy that I think it is exceedingly unlikely, because vaccination is not what we ordinarily call vivisection. I know it is really, as the animal is now prepared, vivisection; but it is not generally called that. It ought to be, for it is much more painful, I believe, than antitoxin. Antitoxin, though we hold it to be unjustifiable, is not by any means the most painful of experiments. I rather differ from Mr. Lewis there, but the poor calf has its head fixed in a kind of vice in order that it may not, in the irritation of a number of pustules (which they tell me vary from 40 to 200) on the stomach, have the relief of rubbing them off.

8893. (*Sir William Collins.*) Do you happen to know whether Dr. Hime, besides raising stocks of vaccine lymph, also made experiments on calves with a view to seeing whether he could get vaccine lymph by inoculating calves with small-pox?—I know nothing of it.

8894. (*Dr. Wilson.*) In referring to that book of Miss Lind-af-Hageby, you said that you had the first edition on sale?—Yes.

8895. Where?—We have a stall at the Ecclesiastical Art Exhibition of the Church Congress. I have always been very anxious to show that it has not been withdrawn. I refused to return the copies I had, and I have always had it for sale.

8896. You want to test the question whether it is libellous or not?—I want to show that it is not libellous.

8897. (*Chairman.*) Is that a reprint of the first edition?—No, it is the very first edition. When Mr. Bell, the publisher, called all the copies in I refused to send in the copies I had bought. I hold them. I am very precious over them because they are very few, and I am not anxious to part with them, but I am anxious to show the public that they can buy it, and I have it there if they wish for it.

8898. (*Sir John McFadyean.*) Have you actually sold a copy?—Yes, I have sold one.

Mr. G. H. Burford, M.B., called in; and Examined.

Mr. G. H. Burford, M.B.

8899. (*Chairman.*) You come to give us evidence at the request, I believe, of the World League of Opponents of Vivisection?—Yes.

8900. Is that a London Society?—I believe so.

8901. Is London its capital?—That is my impression.

8902. Are you a member of it?—I am not a member.

8903. But you come at their request?—I do.

8904. Do you know anything of the Society—the numbers of it?—I am afraid I cannot give you any information on that point except that I have reason to believe that it is a society of some consequence.

8905. It has a wide-spreading title. I do not know whether its members cover all the world or whether they are mainly in London?—I am unable to give you any explicit information on that point; I know some of its members, and they are, in my judgment, persons of some consequence.

8906. But whether the numbers are 100 or 1,000 or 5,000 you do not know?—It is perfectly immaterial to me.

8907. It may be to you, but to us it may be material, because, as I understand, you come at their request and to represent their views?—That is so. I am not aware of the magnitude of membership.

8908. You have sent a very short note of your evidence, and I understand that the important point that you wish to bring before us is your objection to experiments for purposes of pharmacology and the statement that experimentation might be superseded altogether without any cruelty and with as good effect by following the methods of homeopathy?—That practically is my position.

8909. We are not here, of course, to inquire into the merits of the homeopathic form of treatment, but only as regards this question of experimentation on animals. Would you just tell us what is the method by which the homeopathic pharmacologist would test drugs?—For the purpose of investigating the remedial value of a drug from the homeopathic point of view, the experimenters are always healthy human beings; healthy in the first place in order that the vitiating results of sickness may be eliminated, human in the second place in that the major part of a medical man's work deals with human beings; and conscious human beings in the third place in that the great variety of subjective

symptoms and mental conditions which are unattainable by experimentation on animals may be added to the objective findings.

8910. Are you speaking of these experiments as being carried out on those who are already patients, or purely as experiments on people whom you are not seeking to cure of anything?—Only on volunteer experimenters.

8911. That is to say on persons who are not coming there for the purpose of being cured?—That is so. Investigation on the nature and scope of drug action is carried out solely on what I might call volunteer experimenters. Of course, in many instances these volunteer experimenters are medical men and women, and so are persons competent to observe their own condition. They must be of average health; that point, of course, is carefully gone into. The results, often of course very unpleasant to the experimenter, are recorded in part by the individual him or herself, and in part by the supervisor of the treatment; that is to say, the detail is committed to paper in as thoroughgoing a fashion as possible. The drug for investigation is taken first in small and then in larger and repeated doses, covering oftentimes a long period—weeks, months, sometimes longer than that.

8912. When you say small and then larger doses, we know that drugs in homeopathy are usually given in very minute doses, although I think most of us know that that is not the essential principle of homeopathy, but when you speak of small and larger doses what would you call a large dose; do you mean a dose as large as the extreme dose that could be given by way of experiment in ordinary drugs?—For the purpose of this investigation homeopathy is left entirely out of the question. We are committed only to the investigation of the action of a drug upon the human organisms before us, totally independent of the account to which this investigation may be turned.

8913. Totally independent of the methods of homeopathy in treating a patient?—Yes. In regard to a dose, the dose to begin with is always one which would produce obvious effects upon the organism; there must be something to record; after the patient has recovered from the effect of the first dose, a second is administered, then a third, then a fourth, usually in increasing quantities. The quantities bear no relation whatever to the quantities usually employed by homeopath. Besides the obvious detail produced by the action of the drug to the experimenter, him or herself, and to the ordinary supervisor, these experimenters repair during the course of the investigation to certain skilled observers—specially skilled observers —who each take in hand the various organs and parts of the body for which they are specially competent to speak, now the eye, now the ear, now the nose and throat, now the chest, now the abdominal condition, now the state of matters in the skin, and so forth; so that over and above the generalised disturbance which the drug produces there are also special reports of the special examiners detached for the purpose of special observation on the parts of the economy for which they are most competent to speak. We have, for instance, carried out in this country—that is, our Homeopathic Association—investigation on the drug colchicum in this way, and with your permission I should like to put in some extracts from the observations made on this drug so as to convey some idea of the character of the investigation and its thoroughness (*handing in some papers*).

8914. Was the object of those experiments to ascertain the effect of colchicum on particular diseases?—No, the pure and unsophisticated effect of colchicum given in material doses on the healthy human body as the basis for remedial application.

8915. Without reference to any particular complaint?—Without reference to any particular complaint. It was a search for pure knowledge apart from the special purpose to which the knowledge might be turned.

8916. Perhaps you can give us an explanatory statement of these papers in your own words?—In the course of that experiment there were five adult individuals engaged, each of whom noted day by day the different perturbations in health to which each was not accustomed, and when the experiment was over all their statements were summarised, indexed, and taken as manifestations of the action of the drug on their economy.

8917. How did you measure the effect upon the body; in what way did you ascertain the effect—by the pulse or by the temperature?—By all the methods which are usually employed for the examination of disease in a sick person.

8918. By what you would call clinical observation?—Exactly; observation of the temperature, the pulse, the blood pressure, an exhaustive examination of the blood character itself, and a very exact volumetric estimation of the urinary constituents passed day by day, together with the objective facts observed by the various special examiners to whom the experimenter in question was referred from day to day.

8919. But without any local observation, of course, of the internal organs while it was going on?—Without any local observation of the internal organs, I mean that there was no vivisectional procedure in so far, of course, as the researches of ordinary medical or surgical examination would apply. For instance, the eye was examined instrumentally, the ear was examined instrumentally, and certain other internal organs which could be got at were examined; but the same methods for examining a patient suffering from a drug disease were used as are customary for examination of patients suffering from an idiopathic disease.

8920. Colchicum, of course, is a drug which has been employed for a great many years?—Yes.

8921. It was not a new drug?—No.

8922. Will you tell us what new knowledge you derived from those experiments?—There were various technical points brought out so far as new knowledge is concerned which I am unable to summarise at present, except that in the judgment of myself and others the knowledge gained and acquired of a technical character was worth the experiment. With reference to another experiment of a similar kind carried out in America recently on belladonna, no less than 53 experimenters were engaged over a period of a few years in a similar investigation. In that instance there were no new facts of any magnitude or of new material character brought to light, but the old facts already known, or, at least, the more important ones, were accentuated and emphasised, and that gave us a clear idea that there was very little more to be got out of a new experiment with belladonna even with all the modern instruments of precision. Negative information of that kind we regard as satisfactory, although not as satisfactory, of course, as if new facts had been brought to the light of day.

8923. As the result of those investigations, have colchicum and belladonna now been imported into practical homeopathy at all?—I have here a book containing the belladonna investigation, if I may submit it to your notice. (*Handing in the same.*)

8924. It is too big for reference as we sit here, but we will keep it?—May I go a little further and say with regard to other remedies that many have been introduced into professional use through homeopathic methods which previously were entirely either unknown or practically ignored. Such remedies as nitroglycerine, for example, first came into the ranks of the profession through a homeopathic medium; and snake poisons, the crotalus snake poison, the lachesis snake poison, and the naja snake poison have also been introduced into professional use through homeopathic media, and the action of metallic gold also owes its professional usage to the same origin. The original observations were made on metallic gold by Hahnemann a century ago, and no material addition with regard to the virtues of gold as a remedy has been made since his time. The secretion of the cuttlefish, the virtues of the sepia as a remedial agent came through a homeopathic source. Original observations on bichromate of potash and its value in disease were made by Dr. Drysdale, of Liverpool, some 40 or 50 years ago, long anterior to its present revival; the bean ignatia came into professional use through a homeopathic source. The honey bee, apis mellifica, although investigated of late, had its action first exhaustively determined many years ago in America under homeopathic auspices. Cactus for cardiac affections, first introduced by Dr. Rubini, came into use through the medium of homeopathic experimentation; Rhus Toxicodendron, a favourite remedy nowadays for rheumatism and skin diseases, also owes its introduction to homeopathic auspices.

8925. You are taking these as being homeopathic remedies or drugs which are used generally in what homeopaths call allopathic treatment?—As being used by the general medical profession, but owing their introduction to the methods which I have in-

Mr. G. H. Burford, M.B.

29 May 1907.

dicated as practised exclusively by homeopathy. Calcium sulphide, a common favourite remedy nowadays for furunculosis, and used for this affection for very many years; nitrate of uranium, a common remedy for diabetes, which has found its way into professional use through homeopathic sources; and another remedy, lycopodium, which is used for fireworks or the coating of pills, has on the homeopathic method, that is to say, experiment on a healthy human being, been discovered to have curative virtues of an important and extensive character. This is merely an excerpt of the services which homeopathy has rendered to the profession at large in introducing a large number of new drugs of the virtues of which the general profession were previously not aware.

8926. Has homeopathy adopted the discoveries in drugs made by physiologists or pharmacologists who have followed the experimentation on animals other than man?—Homeopathy finds that experiments on healthy human beings yields results more ample, more direct, more fertile, and more reliable than the details obtained by experiments on animals.

8927. I may perhaps take an example which Dr. Cushny gave. You know Dr. Cushny by name?—I know Dr. Cushny by reputation very well.

8928. He gave us evidence at considerable length of importance as a pharmacologist and as a pharmacologist pursuing his inquiries by means of experiments on animals, and one instance I remember that he gave us was the use of digitalis, which he explained. I am not going to attempt to explain it in medical language at all, but he explained that, whereas digitalis was recommended as a remedy and used as a remedy or as having a particular effect on one particular complaint, it was found that in certain cases it would have a dangerous effect, while it affected other organs beneficially if properly applied. That was discovered by experiments. Supposing you were making an investigation on the operation of digitalis homeopathically, how would you do it?—I should begin by giving digitalis in a substantial dose (we know something of digitalis to start with) to a healthy adult, noticing the disturbances that it created upon his organism, taking his temperature and pulse, and having all his organs, so far as they could be individualised, examined by a corresponding expert; in fact, all the detail that has served the medical man for the diagnosis of a disease would be applied to the diagnosis of the drug conditions induced by digitalis; and the conditions which are produced in animals by digitalis given in this way would find more than their correlatives in a human being when sufficiently big doses of digitalis were taken for purposes of experiment. Then after the man had been made sufficiently ill, when it was obvious that there was nothing more to be got out of the investigation so far as he was concerned, the experiment would be stopped. Probably it would take him some months to get quite well again, and all the various instrumental observations on his pulse, on the beating of his heart, on the varying size of the heart musculature during its operation would form part of the supervisor's report; that is to say, the investigation would be carried out with the same thoroughness and the same detail as an investigation on a corresponding animal.

8929. I do not know whether you have read Dr. Cushny's evidence given here?—I have.

8930. Then you will remember, I daresay, what he said about the ocular demonstration that was given by experiments of the effect of digitalis on the blood vessels in certain cases?—Yes, I do. I can only say—Dr. Cushny is not here, therefore I must speak guardedly—that I am sure Dr. Cushny spoke in ignorance of the very considerable homeopathic literature that has accumulated since Hahnemann's time as the result of the observation of the action of digitalis on the human body; it fills volumes; and so far as the addition of modern methods of precision by instrumental appliances is concerned, it is found, in carrying out these investigations, that all the essential points as to the remedial action of digitalis can be obtained by observation on the healthy human being.

8931. After reading Dr. Cushny's evidence, then you consider that the experiments of which he gave a full description did not add anything to the knowledge which you already possessed. I am reminded that the experiments which he described were not his own experiments?—They added something to the knowledge we already possessed, but nothing of any material importance; they added something in point of academic completeness to this knowledge, but they did not add anything to our knowledge of the remedial virtues of digitalis. The experiments cited by Dr. Cushny placed no additional weapon in our hands so far as digitalis is concerned for the treatment of the disease.

8932. You mean no additional knowledge as to the operation of digitalis in such and such quantities and in such and such diseases?—No other knowledge than was already at our disposal.

8933. I daresay some other gentlemen who are much more competent to ask you questions than I am will ask you questions upon that?—I am sorry that I have been unable to express myself with greater precision.

8934. No, I quite follow what you say. Does that answer which you have given about digitalis apply to other discoveries made by animal experimentation—that it has added nothing to your knowledge for practical purposes?—If I may say nothing material, nothing of importance to our knowledge, that answer in general, with certain exceptions, would apply.

8935. I think that is the gist of your evidence; other gentlemen will ask you questions, I daresay, and elicit more information, but I will not myself ask you any more questions.

8936. (*Mr. Ram.*) Have you yourself ever seen any vivisections?—Yes.

8937. In England or on the Continent?—Both.

8938. (*Chairman.*) I did not ask you the question—are you a practising homeopathist?—Yes.

8939. (*Mr. Ram.*) How long ago is it since you have witnessed any vivisections in England?—During the time that I was a student.

8940. That was before the present Act?—Yes.

8941. Have you witnessed any since the present Act, in England?—No.

8942. Will you kindly tell me the deductions that you draw with regard to the use or abuse of vivisection, from what you have been telling us just now?—With regard to the abuse of vivisection, my deduction is that the major part of the detail derived by vivisectional procedure on animals has still to be verified in its application to man; and that being the case it would be better, in our judgment, to obtain that information at first hand from man himself, and to leave the introductory information from animals on one side, as being sometimes contradictory and occasionally very misleading.

8943. You spoke of verifying the results which have been obtained by examination of animals?—Yes.

8944. Then you think that there has been something obtained, though you may think it may need verification?—Something without doubt has been obtained, and, in some respects, something very considerable, but it is not the best way of determining the remedial powers of drugs.

8945. Have you informed yourself, otherwise than by reading the evidence which has been given before the Commission, of the discoveries which are supposed, at any rate, to have been obtained by experiments on animals?—I am a tolerably diligent reader of the Medical Press, both English and foreign, and I do not think much of moment has escaped my observation which has been recorded of that character.

8946. I may take it then that you have informed yourself of the literature. Do you think that there has been useful knowledge arrived at by experimentation on animals, or not?—I believe that it is impossible to obtain knowledge from vivisection on animals which cannot be turned to some useful account; knowledge is in its nature, of course, a thing which can be utilised; but I maintain as regards drugs that knowledge would be better and more completely obtained in another way. It is a case of relative importance.

8947. You admit then that there has been some useful knowledge obtained by experimentation on animals?—I admit that there has been useful knowledge obtained. No medical man I imagine could take any other view.

8948. You spoke of making experiments on different patients of different drugs?—Not patients; experimenters—healthy people.

8949. I use the term patients in the sense of those who endure what they have to bear?—Exactly; but they were not experiments on sick people.

8950. I take it so. You spoke of trying digitalis, for instance; have you ever had the chance of verifying by post-mortem the conclusion you arrived at by any of these experiments of yours on living people?—If you mean the school to which I belong—yes, many; chiefly from involuntary experiments in cases of chronic poisonings.

8951. Have you found by post-mortem examinations useful knowledge of the effects of the drugs you had been administering?—Useful in a way, but not nearly as useful as that obtained by clinical observation of the experimenters whilst the experiments were being conducted.

8952. You spoke in one case of a man who might be in such a state that it would take him three months to get well again?—Yes.

8953. Was he a volunteer?—Yes.

8954. Conscious of what he was submitting himself to?—Yes, a medical man, and doing it with open eyes. I am pleased to say that hundreds of medical men since the time of Hahnemann have done the same thing.

8955. This man took several months to get well again?—He is not well yet—but that does not count.

8956. Not in your view?—No.

8957. Would you have the right to try an experiment on a man who was not a volunteer?—As an ethical question, in my view of ethics, it would be decidedly immoral.

8958. Do you think that in all cases it is wrong to try an experiment on an animal even if that animal suffers nothing whatever, but is under anæsthetics the whole time and dies under anæsthetics?—That question is rather a large one, and I think the answer would depend entirely upon the specific purpose for which the experiment was conducted.

8959. Supposing a case in which a skilled experimenter believed that he could obtain useful knowledge, either as to the action of a drug or the nature of a disease, and he puts an animal under anæsthetics, and the animal dies under anæsthetics, and suffers nothing, is it right or wrong for the experimenter to try and obtain that knowledge?—Do you wish me to answer an ethical question?

8960. I thought you were here to do so; you have been putting the ethical point of view. If you would rather not answer, I do not press it?—I am perfectly willing to submit my own answer. If the experimenter was a competent person and was convinced in his own mind that he was doing what was right, it might be a right thing to do.

8961. (*Colonel Lockwood.*) Have you any suggestions to make to this Commission as to any additional safeguards which could be provided supposing that vivisection, as it is popularly called, was continued?—I think that prior to the experiments on animals with any new drug, there should be experiments carried out on human beings, not afterwards, but before, and that any point left undecided in the experiments on human beings might then be considered possible (I say, possibly) as a fit and proper subject for experimentation on animals; but I believe that investigation with drugs on healthy human beings should in all cases precede the experimentation on animals.

8962. But you believe that all experiments on human beings should in all cases precede experiments on living animals?—That is as regards drugs on volunteer human beings, of course.

8963. (*Sir William Church.*) Do the principles of Hahnemann still remain as principles in homeopathy?—Yes, that is to say, not all of them, of course, nor all in the condition in which Hahnemann left them; homeopathy, like medicine in general, is a progressive science, but the main principle of homeopathy; that is to say, the law of similars, which is, of course, the centre and pivot of homeopathy, homeopaths hold as scientifically valid.

8964. But, I suppose, it is admitted by them that there has been progress in medicine since?—Distinctly.

8965. In our knowledge of disease?—Distinctly, very much so.

8966. So that some of his main principles you have thrown overboard?—I imagine that blood letting and mercurialisation, and things of that kind, have gone by the board, too.

8967. How about psora?—Psora was a technical term used by Hahnemann for expressing the degree of pathological enlightenment at the time, or which we now consider as diathesis.

8968. He took as his principle what he called an established fact, that there does not exist a single disease which could have a material principle for its cause. That is no longer held by homeopathy?—That has gone by the board as being not in keeping, of course, with modern knowledge; but its retention or its omission affects in no material degree the practice of medicine; it does not affect the usage of the law similia; it is not an essential part of homeopathy. It was one of Hahnemann's views.

8969. Neither was psora an essential part of homeopathy?—Not as a pathological notion.

8970. I do not want to ask you anything further about pharmacology or the use of drugs, but we have advanced beyond the use of mere drugs, or the world thinks we have advanced beyond that. Do you not agree that serum therapy is of use?—Yes, as a private individual I do most emphatically.

8971. Could that have been arrived at without experiments on animals?—It is quite possible that it could have been arrived at in another way, and that the same properties which are utilised in serum therapy might have been used without having recourse to animal experimentation. I will cite one instance of that. The virus of consumption, that is to say the tubercular virus, was prepared by homeopathists and employed by homeopathists for the treatment of consumption long before Koch's discovery of the tubercle bacillus.

8972. I will take your answer?—I believe that what I am saying is capable of verification, and I am quite prepared to fight it out elsewhere if my statement is taken exception to.

8973. (*Dr. Wilson.*) Do you mean that the tubercle bacillus was discovered?—Not the tubercle bacillus, but the virtue of the material in which the tubercle bacillus was contained. The tubercle bacillus was not isolated, but the material in which it is contained, the lung substance, for instance, was prepared by homeopathic methods and used successfully before Koch launched his discovery. I will only quote Von Behring, who will have it that all this is homeopathy, and that Hahnemann's word homeopathy should be employed to indicate it. It is the cure of a disease by a substance which it itself manufactures and as nearly an instance of a similar remedy as could very well be selected.

8974. (*Sir William Church.*) You think then that our present knowledge of such substances as all the antitoxins could have been obtained without the use of animals?—Exactly how antitoxins may best be obtained is still an open question. It is possible that researches in the next 50 years may indicate quite other methods.

8975. I do not want to know anything about 50 years hence; I want to know whether in your opinion the present position of our knowledge with regard to antitoxins could have been attained without experimentation on animals?—Using antitoxin as a remedy which cannot be bettered in any way, of course all the knowledge with regard to antitoxin has been derived through experimentation on animals. I maintain though that antitoxin in its present form is not a final and ultimate preparation. There are other methods of preparing virus which, in my judgment so far as cure is concerned, are equally valid.

8976. Have these other methods been brought into use and generally accepted?—In the case of tuberculin, yes.

8977. We will pass from that?—I take that as a typical instance.

8978. You take tuberculin as a type?—As a remedial method of nature.

8979. Was it attenuated?—It was titurated with sugar of milk in a mortar, and the same dose readily obtained that Professor Wright now advocates—that is, anything from $\frac{4}{1000}$ th to a $\frac{10}{1000}$ th of a millegramme.

8980. Any other?—Homeopathic original research is unfortunately heavily handicapped in this country. We have no school and no well-salaried laboratory, and we have had to be content with our research in tuberculin. I take that as an instance of what might be done with other serums and viruses.

Mr. G. H. Burford, M.B.

29 May 1907.

8981. Apparently you have done a great deal in the way of introducing drugs into medicine. Have you introduced a new soporific, or anything of that kind, which has been of use?—I am afraid I can scarcely answer that question in the way it is put. If you will permit me to frame my answer in this way: The method of drug experimentation on human beings which homeopathy has introduced has very largely cleared away for remedial purposes those particular labels of soporific, diuretic, and so forth, which one was formerly accustomed to hear. This view starts by assuming that a drug has only either one property or one main property, but the results thus gained on animals with any particular drug can be enormously amplified by experiments on a human being, and thus results not obtained by animal experiments can be observed and verified on human beings, which results involve a far wider area of affection than was observed in the case of experiments upon an animal. Therefore we do not label drugs as diuretic, soporific, and so forth, but by what we call their *tout ensemble*, and we endeavour to fit in that *tout ensemble* with the case of any particular disease which may be placed before us. Wherefore homeopathy knows nothing of soporifics, but it knows a good deal of similar conditions.

8982. One of the bases of your work is the study of symptoms, is it not?—The study of symptoms constitutes a part.

8983. Therefore, of course, you do not go in for experimental work on animals?—No; but we go in for the observation of objective changes on the human being at the same time as the symptomology is being evolved.

8984. Are you acquainted with anything that has been done with regard to the neutralising of snake poison?—I cannot say that I have in my memory at present anything that has been done from a homœopathic source.

8985. You know that such a substance as antivenin has been discovered?—Yes.

8986. Do you think it is of any use?—I am really not competent to pass any opinion, because it is a branch of practice in which I do not daily engage.

8987. Perhaps you do not care to answer the question whether you think that could have been obtained by homeopathic methods without the use of experimentation on animals?—I prefer to reserve my judgment on that point, because I am not acquainted with the detail.

8988. (*Chairman.*) Is your society, the World League of Opponents of Vivisection, essentially a homeopathic society?—No, it knows nothing of homeopathy.

8989. (*Sir William Collins.*) Are the views that you put before the Commission this afternoon those of the Homeopathic School of Medicine generally?—Not necessarily. The School of Homeopathy takes divergent views on many questions which I have answered; but you may take my views as expressing the views of the major number of medical men practising homeopathy in Great Britain and America.

8990. And also as the views of the World League of Opponents of Vivisection?—That I cannot say.

8991. I thought you appeared to represent them?—Yes, but I have not informed myself of what the views of each individual member may be; I can only express my own views.

8992. Is the evidence you put before us then to be taken as representing the views of the World League?—So far as regards the desirability of transferring the scene of action of experiments with drugs from animals to man as a general procedure, I believe so.

8993. Do you contest the proposition that useful drugs have been introduced into therapeutics as the direct result of experiments on animals?—I do not contest the proposition, but I say that many more useful drugs have been introduced into general medical practice through the medium of homeopathic experimentation on the adult healthy person.

8994. You think that the method of experimentation on animals should be abandoned in favour of the method that you advocate?—I believe that legitimate knowledge should be legitimately obtained from any source, but, as I said just now, in case of experimentation to be conducted on a new drug for the purpose of discovering its remedial virtues, it should be conducted in the first place on a healthy human person.

8995. But do you take up the view that experiments on animals for a scientific purpose should be restricted or prevented?—I believe, as the result of my observation and experience, that it would be legitimate to very heavily restrict them in one direction—that is to say, that information derived from animal experimentation with drugs could and should be obtained from experimentation on human beings. They ultimately have to come to it, because animal experimentation results have to be verified on the human being as the ultimate issue.

8996. It has been alleged, for instance, before the Commission, that cocaine, adrenalin, sulphonal and other remedies, have been introduced as the direct result of experiments on animals. Do you suggest that those remedies are not useful or that they have not been obtained by that method?—I do not suggest that they are not useful, and I do not suggest that they have not been obtained by that method. I should be very sorry to do anything of the kind. I do suggest that they could, and should have been, obtained through the medium of human experimentation. You get your results then unsophisticated.

8997. How would the preparation of antitoxins be affected by the method which you advocate?—As I say, the opportunities of the Homœopathic School for Research are unfortunately rather limited, but in all probability the preparation of antitoxins would undergo what one might call homœpathising—that is to say, that when homeopaths turn their alternation more extensively to the subject probably some alternative method similar to that used for the preparation of tuberculin could and would be devised; we take that as an indication of what can be done with toxins of this description when they are submitted to homeopathic preparation. So far as diphtheria antitoxin is concerned, I am unable to give you any information with regard to a better preparation after the homeopathic fashion; it has not hitherto been attempted.

8998. If we wanted to get an antitoxin for use to-day we could not get it by the methods that you advocate?—Not as yet to-day.

8999. (*Sir John McFadyean.*) It has been suggested as one of the objections to animal experimentation conducted on healthy animals, that the conclusions based on such experiments cannot legitimately be applied to a diseased condition; do you think there is any force in that objection?—I believe that they cannot be applied by inference to a diseased condition in man, and, of course, it is to the human being that the results of all these experiments are applied.

9000. But putting aside the question of difference of species of animals, do you think there is any force in the contention that conclusions drawn with regard to experimental conditions in healthy subjects cannot properly be applied to diseased states of animals of the same species?—No, I should not hold that.

9001. You think there is no force in that objection?—No.

9002. Your idea of the proper method of investigating a new drug is that it should be tested in increasing doses, beginning, I take it, with what you regard as perfectly safe doses, on human beings?—That is so

9003. After all, that is an experiment, is it not?—That is an experiment, necessarily.

9004. But you think it is moral because the individual consents?—Exactly.

9005. It would be immoral without his consent?—That is my ethical position; it is a personal position, of course. That is what I personally wish here to convey as my own conviction.

9006. You also hold very strongly that results obtained on the lower animals may be misleading when applied to human diseases?—May be and often have been misleading.

9007. Does it not appear to you that you have barred out all method of investigating animal diseases and the action of drugs on animals?—For the purpose of investigating animal diseases it is quite possible that in the interests of the animals another system of ethics might prevail. So far as regards human diseases, I hold that this is the only legitimate method.

9008. It is a very important question. I daresay you can realise that in veterinary practice from the point of view of £ s. d. it is a very important matter?—Exactly.

9009. I want to ask you whether you think that the method of investigating a drug intended for human use which you advocate, might be extended to animals?—No, I should have the same scientific objection to extending observations on human beings to animals.

9010. But you rather misunderstand my question. I understand your position to be that when it is desired to obtain information as to the usefulness of a particular drug on a particular species, it must be tested on healthy individuals of that species?—Yes.

9011. Have you any objection to allowing that general principle to be extended to the investigation of what I may call veterinary drugs?—For a knowledge of the diseases of the lower animals, knowledge obtained from the lower animals is, of course, essential, and is a scientific necessity. That is not unethical; I would not maintain that position for a moment, I think it would be untenable. I do not, as my personal opinion, regard that as immoral.

9012. So that you think that experiments on animals which are intended to increase one's knowledge as to the means of curing and preventing animal diseases, are legitimate?—Much would depend upon the object of the research and on the investigator.

9013. I say that the object is to gain increased power of curing and preventing diseases of that particular animal species?—I do not see any alternative to obtaining valuable information as to the diseases of animals except through the animals themselves.

9014. Then you do think it is legitimate? I think you are bound to make that admission, because you lay down the general principle with regard to the proper line of investigation in man, and you are bound to admit that it is the only proper method of investigating the use of drugs which are intended to be applied to the cure of animals?—That is so.

9015. You have mentioned a number of remedial agents which you said have been introduced through homœopathic sources. I did not quite understand what you meant by introduced through homeopathic sources?—I mean that the knowledge of their properties was first gained by the homeopathic method—that is, experiments on healthy human beings, and then published for the behalf of the profession at large.

9016. But in that respect there is nothing different between homeopathy and other practice. There must be something in the first instance to suggest that a drug might be tried or might be useful?—If a man goes into a laboratory, opens a bottle, and takes a good sniff of some very powerful odorous medicament——

9017. Such as gold?—Such as tri-nitrin.

9018. But please take gold?—What it was that induced Hahnemann in the first instance to take gold I do not know, but I know what induced Professor Albert Robin to take up the investigation of the remedial virtues of gold; it was the results obtained by homeopathic practice——

9019. Such as?—The cure of tertiary syphilis.

9020. The cure of tertiary syphilis with what?—With gold.

9021. Then it was not through homeopathy that gold was introduced as a remedy?—Yes, it was.

9022. What led to its introduction?—That I could not say.

9023. It could not be a knowledge of its efficacy in the cure of syphilis that led to its introduction?—What was in Hahnemann's mind when he took up and investigated the properties of gold I cannot say.

9024. My point was that there did not seem to be anything special about your principle of homeopathy introducing a drug. I can quite see that there may be something special in your method of testing it, but you have not explained anything special in the method of trying a drug or introducing it in that way?—Of course, the same impetus impels the homeopathic experimenter as affects the experimenter on animals; there is a preparation brought before his notice; and he may be and is desirous of testing whether it has remedial virtues or no. What was the motive in Hahnemann's mind in that particular instance with regard to that particular preparation, of course, I cannot say.

9025. You do not suggest that those who believe in homeopathy have any special method of investigating surgical conditions and diseases?—The same method that is open to the profession at large.

9026. It did not appear to me to be quite clear why you were so emphatic in stating that when it is desired to investigate the action of a drug which is intended for use in man the experiments on human beings should precede those on animals? Is there any moral law concerned there?—I did not give that preference on the basis of a moral law, but on the basis of scientific results.

9027. But must there not always be a slight element of danger in using a perfectly unknown drug on a human being?—There is always an element of danger, but after some practice, of course, experimenters become more or less facile.

9028. They cannot be facile with a new drug?—But they can go to work in such a way as experience has indicated, just like explorers in a new country can form some idea of the probable dangers in front of them.

9029. It is not obvious how a man can estimate the probable safe dose of an entirely new drug?—It is obvious that it is a matter of experience. Supposing that a man has a new drug and dilutes it one million times, the probability derived from previous experiments is that a millionth part will not contain a lethal dose.

9030. It all depends upon what was the strength of the material before he began to dilute it?—Supposing he finds a white powder in a paper submitted to him, as being some material which hitherto has not been investigated, he has not the faintest idea whether it is innocuous or lethal. The first thing that he would do would be to take this crude substance and considerably dilute it, let us say one million times, and the records of previous experience with drugs would lead him to understand that in all probability a millionth part would not be a lethal dose. He might therefore with propriety begin his investigations, and then he can heighten the dose according to his judgment.

9031. But, admitting that the danger of subjecting him to too large a dose is slight, why not begin with a smaller dose on an animal; it is not denied, is it, that it forms some guide as to whether the thing will be dangerous or not?—It is denied that it affords some guide as to what is safe for use among human beings. The whole of the animal experimentations as a matter of fact have to be verified in some form or other and at some time or other on the human organisms. Why not, therefore, begin with the human organisms at once?

9032. I have tried to convey that in my opinion you should begin with an animal because it safeguards the human being, and that you do not lose very much time by it?—You do not lose very much time by it, and in the majority of instances you gain little.

9033. You have frankly admitted that the class of so-called protective sera have been discovered entirely by animal experimentation?—Yes.

9034. But you ask us to believe that it is quite possible that they might have been discovered by other means?—Yes, that is my position.

9035. There does not seem to be much force in the suggestion that they might have been discovered by other means. Everybody, yourself included, has had these other means at disposal, and yet you have to admit that nobody discovered anything in the nature of a protective serum until it was discovered by animal experimentation?—If homeopaths had had at their back all the immense resources, the revenues of a province often, which allow these investigations to be carried out, I do not think that homeopathy would have been behindhand in indicating in all probability another and a better way.

9036. But you do not require a very great laboratory, and you do not require a laboratory to be richly endowed in order to do valuable research. Some of the greatest discoveries have been made by people who have had very limited equipment?—But the work with regard to antitoxic sera has been done by people detached from ordinary daily life and the pursuit of their profession for this specific purpose. That is a little expensive. You have to pick your man also; he must have special faculties and ability for that work. Our body in England is not sufficiently big to detach men from daily life and practice for this specific research work, except occasionally.

9037. But you are aware that there is a great deal of money behind this question. If homeopathy can produce efficacious things like the various protective sera, an immense amount of money can be made out of it. Does the fact that they are not invented not tend to diminish the hope that our knowledge in that direction

Mr. G. H Burford, M.B.

29 May 1907.

will be extended in any other way than by animal experimentation?—I should be sorry to think that the basis of scientific experiment was the love of gold.

9038. I did not mean to suggest that it was.

9039. (*Sir Mackenzie Chalmers.*) You are not yourself a member of the World League of Opponents of Vivisection?—No, I am a member of no anti-vivisectional body.

9040. How did they come to ask you to give evidence on their behalf?—The application came through a friend of mine, a homeopathic colleague, a member of the League. I asked to take this homeopathic point up with regard to the subject, and, as a matter of fact, he requested me to do it myself, and I had no objection.

9041. Practically your evidence is evidence on behalf really of the mass of homeopathic practitioners?—You may put it so.

9042. I want to ask you this: Speaking on behalf of people whose opinion you represent, what changes would you advise in the existing law. We have to consider the Act of 1876 and whether it requires amendment. Will you kindly tell me whether you suggest any amendment?—Are my suggestions to be put from a practical point of view?

9043. Yes, because we have to advise the Government?—The main suggestion that I would make is that when experiments with regard to the remedial action of drugs—I am not dealing with other elements now—are concerned, they should in the first instance be carried out on healthy human beings. That is my point.

9044. Would you have it enacted by legislation that a licence should not be granted for an experiment upon an animal until a corresponding experiment had been made on a healthy human being?—I would leave that to the discretion of the Inspector; I do not think that a hard and fast rule could be laid down in every instance; but I think that discretionary power should be given to a responsible individual in the case of every specific question of this kind being submitted to him, he being fully and entirely responsible for his decision.

9045. The Inspector merely inspects what is going on. I do not understand your suggestion. How would inspectors deal with it?—May I put it in this way: that the advisers of the Home Office should be held responsible in each instance for the vivisectional investigation on the lower animals of the properties of a new drug, and that they should give their specific reasons in each case why the prior investigation on a healthy human being was not adopted.

9046. You agree that that would limit experiments enormously, because there is not a large supply of healthy human beings willing to be experimented upon with unknown drugs?—I think you would find that in the interests of science a sufficient supply of healthy human beings was forthcoming. In America the supply of medical students in the Homeopathic Colleges is a never failing source of adequate material.

9047. You think it is not only justifiable, but right, that in the first instance a drug which may be remedial or may be toxic should be tried on man?—I believe it is not only justifiable but right, if it is carried out under the supervision of a competent experimenter. Anybody can bungle, of course.

9048. (*Chairman.*) Where do you get the volunteers from; are they from among medical students or from people who are paid to undergo it?—Some of them are medical students; some of them are persons who do not require any financial inducement; and some of them require just sufficient financial assistance to recoup them for detachment from the duties which they ordinarily discharge.

9049. (*Sir Mackenzie Chalmers.*) Just to test those principles a little further, take the case not of a new drug but of a specific poison like snake bite; would you say that it is justifiable to try an experiment on the lower animals with a view to testing a remedy for snake bite?—We do not go to work quite in that way. I am sorry to appear unsatisfactory in my replies, but it is not always possible to answer a question in the way in which it is put. In indicating what was useful for snake bite, homeopaths would run all over the details of the drug experiments, many thousands in number, which they had in their possession, and see which of those paralleled the condition of snake bite, and they would put their finger upon the series of experiments already made which most paralleled the condition of snake bite as indicating the remedy; it might not even be necessary to carry out any new investigation. If I may give an instance, when cholera in the thirties swept over Europe, Hahnemann was applied to for effective remedial measures to meet the cholera epidemic. He indicated a satisfactory remedial measure from homeopathy, without additional experiments, from what had been already made.

9050. With what result?—He got, if I may put it, very much better results than the current therapy of his time, and homeopaths afterwards in London repeated them, with such success that they were made the subject of a special Government Inquiry. All this is ancient history.

9051. And are his methods still applied in India where cholera is always present?—Yes.

9052. By whom?—They are mainly applied by those people in the Army with homeopathic leanings, of whom there are some; and also by such educated professional native gentlemen as engage in homeopathy, of whom there are not many; but there are some.

9053. I suppose you admit the utility of vaccination?—Is it my personal opinion that you want?

9054. I only ask it as the basis of a further question?—In the majority of instances I admit the utility of vaccination.

9055. Vaccination has been known for about 100 years?—Yes.

9056. Have homeopaths by their methods discovered any equivalent substitute for vaccination?—Homeopaths hold vaccination to be as striking an instance of homeopathy perhaps as could well be devised; the majority prefer to carry out vaccination in the ordinary way by subcutaneous injection of vaccine matter. Some of us prepare the vaccine matter according to the method that I have indicated for tuberculin—that is to say, by purely homeopathic process—and, it is said, with equally satisfactory results.

9057. (*Chairman.*) And it is swallowed?—Yes.

9058. (*Sir Mackenzie Chalmers.*) As a prophylactic or as treatment?—Both.

9059. May I ask from what it is prepared? I do not quite understand how the method applies in this particular case. Would you take a case treated in this way and tell us what is done?—Let us say, for instance, that an ordinary small child presents him or herself with three or four healthy vaccination vesicles; the material is taken from all these, dried, diluted, usually triturated in a mortar with sugar and milk, and when it has reached a certain degree of attenuation—how far attenuation is made depends upon the ideas of the individual—when it has reached what he considers a satisfactory attenuation, that is taken as the remedial agent.

9060. How is it introduced?—It is swallowed. When you dilute it two or three million times there is no longer objection to its being introduced into the economy through the mouth.

9061. Have you any figures showing how far this vaccination by homeopathic doses which are swallowed has any effect?—As far as vaccination is concerned, I cannot produce figures on that point (although I know that this thing has been done), because a good many of our homœopaths, as I say, still prefer the ordinary and what they consider to be the least troublesome way of introducing the vaccine matter into the arm; they hold that that is just as homœpathic as if it is administered through the mouth, only that a more considerable proportion of the drug is required.

9062. (*Chairman.*) Is it accepted as a substitute for vaccination?—That is a point that rests with the homeopathic public; some do and some do not.

9063. I meant was it accepted as a substitute by the authorities who require vaccination?—No, they want some local evidence of what has transpired, and we can afford them none in that way.

9064. (*Sir John McFadyean.*) You spoke about the necessity of greatly diluting the material from the child's arm. Have homeopaths or any other people ever produced any evidence whatever to show that material taken from a child's arm and given by the mouth to another will do it any harm?—Evidence of that kind is obtainable just as evidence is obtainable of any other remedial action.

9065. It is not remedial; it is an ineffective method. Can you give the Commission any reference to any experiments on human beings showing observable effects produced on human beings, by giving them an undiluted dose by the mouth of vaccine matter?—Do you mean immediate effect?

9066. Or remote; any effect whatever?—No obvious effect.

9067. Can you refer me to any effect at all?—When it has been tried in that way the homeopathic advisers maintain that the patients are immune.

9068. It is not a question of immunity with small doses. I want to know why there is a necessity for diluting it. Is there any evidence to show that it is harmful if you give it undiluted?—No, none.

9069. (*Sir Mackenzie Chalmers.*) Have any experiments been recorded showing any effect from these minute doses?—Any prophylactic effect, yes; that is to say, any protective effect. Many of them in America; I do not carry the detail with me.

9070. Not in England?—Not in England.

9071. There is only one other point that I just want to get your opinion upon. Homeopaths of course study physiology?—Yes, they have to do so.

9072. Do you think that experiments on animals for the purpose of elucidating physiological problems are justifiable or not?—Am I compelled to answer that question?

9073. I ask your opinion, that is all?—As a matter of fact it is still a moot point with myself; I have not made up my mind.

9074. I take your answer. Would you agree that physiological knowledge has been advanced by experiments on animals?—Nobody can deny that.

9075. Whether those experiments were morally justifiable or not is a moot point in your mind?—That is so.

9076. But nevertheless we are bound to avail ourselves of what has been done in the past?—There is no earthly reason why we should not. We still use rubber, although it comes from the Congo. I trust I have made it perfectly clear that homeopaths at least hold that their method of obtaining information with regard to the remedial virtues of a drug—that is to say, by experiments on healthy human beings—is in their opinion of immeasurably greater value than the alternative method of experimentation on animals.

9077. That I understand to be your opinion. May I take it, then, that your evidence to-day is really confined to that aspect of what we may call vivisection which relates to the action of drugs—pharmacology?—Yes, that is so.

9078. And whatever opinion your Society may hold, you are not here to go into other questions?—I speak for myself.

9079. Among homeopaths you have surgeons as well as physicians, of course?—Yes.

9080. Is it ever justifiable, do you think, before trying a new operation on a human being, to try it on an animal under anæsthetics, or would you try it first on the human being?—I should imagine that most competent surgeons (and I think that no one but a competent surgeon—that is to say, a thoroughly skilled, experienced person—would do it) would answer your question that most decidedly it would be better to try the experiment on a human being and not on an animal. I may say that I have myself some experience in surgery, and that personally would be my decided conviction. A man knows exactly what are the necessary limitations when he operates on the human body. He has some preliminary knowledge to tell him whether his proposed experiment is in flat defiance of what nature can bear or not. An experienced person would know exactly the tax that he proposed to levy on the economy before he started, which only experience could afford; and if he was simply skilled in operating on animals he would not know the exact tax that he proposed to levy on the human economy. He would be more likely to get a satisfactory verifiable result by his human procedure than by his animal procedure.

9081. I was thinking of this sort of thing. You have from time to time new kinds of sutures; you substitute, say, a catgut suture for a metallic suture. Is it justifiable to try that first on a human being, or would you try it first on an animal?—One of the most distinguished surgeons of the day, Professor McEwen, of Glasgow, had to deal with the same subject and answer that question. He made no animal experiments.

Mr. G. H. Burford, M.B.

29 May 1907.

9082. I am asking you, do you think he was right?—Certainly.

9083. It is better to try at first on the human being?—Most decidedly. When you have dealt with animals you have to deal afterwards with human beings, and thus you have to deal with different tissues; and after you have produced animal results you have to produce human results, to see whether those results are verified. It is better to go to the human being at once.

9084. I would like to get your opinion on this point. When you find a new surgical method successful with animals, does it not go a long way towards justifying you in trying it on human beings?—Yes, it would; but I hold that the experience and *naus* possessed by a competent operator would render unnecessary the preliminary procedure on an animal.

9085. (*Dr. Gaskell.*) I was wondering whether, in your method of investigating the action of drugs, you would say that you get accurate knowledge of the action of drugs on different organs or on the patient as a whole?—Both on the patient as a whole, and then in cases of poisoning, acute or chronic, by the *post-mortem* investigations that follow. We accept those *post-mortems*, of course, and what they disclose, as part and parcel of the investigation. Investigation such as this may cover many countries and many years.

9086. Do not you feel sometimes rather doubtful as to whether it is one organ or another that is chiefly affected by the drug?—What you get in the case of poisoning by a drug is exactly parallel to what you get in a condition of disease wherein it is very often impossible until the patient is dead to determine the precise local seat of the mischief.

9087. Is it not better, both in that case and in the case of disease, that subsequent experiments should be made upon animals to see whether that drug does act especially upon one organ rather than another?—That has been done so often, and so little practical information has been obtained—that is to say, the additional power which it has given with regard to the selection of remedies has been so insignificant—that it is no longer held among homeopaths as affording any material additional information of consequence.

9088. What I was mentioning rather was that in physiological experimentation we have the power of analysis which is deficient at the bedside; you can limit your experiments to one particular organ or your drug to one particular organ?—Precisely.

9089. And so you can gain information without complication from other organs; do you not consider that an advantage?—Not much. You often find in cases of disease, particularly a chronic disease, that you do not have to treat one organ solely and wholly. It is the organ in connection with the environment in which it finds itself that the homeopath calls the *tout ensemble*, the totality of symptoms and conditions which has to be treated, and not the simple outburst of one particular organ.

9090. Do not you think that, whereas clinical investigation has been present to the minds of medical men for generations, a great advance has been made of recent years; do not you think that within the last 30 or 40 years knowledge has been very much more quickly obtained than before?—Knowledge has been much more quickly obtained because the armamentarium which advance in science brings with it has been much more copious than before.

9091. Has it not been coincident with the method of experimentation?—It very often grew up side by side with it.

9092. You consider that the experimental investigation has not really largely assisted in elucidating the slow methods of nature's experiments?—Experimental methods on animals, in my judgment, have not added any material information to that afforded by similar experiments carried out on the human subject when they have been taken as the alternative; and when no similar experiments have been carried out on the human subject often nature's experiments were sufficient in number and demonstration.

9093. Would you say that of our knowledge of the tracks and functions of the central nervous system? Have we not gained an enormous amount of knowledge of late years from experiments on animals in that direction?—Physiological and pathological

Mr. G. H. Burford, M.B.

29 May 1907

knowledge, yes. What is the outcome of it with regard to treatment?

9094. I was asking you about our knowledge; you can get a certain amount of knowledge of disease from the hospital bedside?—Yes.

9095. Have we not been able to understand those diseases much more in consequence of our more accurate knowledge of the tracks and functions of the nervous system, owing to experiments on animals?—Without doubt, as far as academic knowledge is concerned, decidedly; no medical student even could take an opposite view.

9096. Has not that enabled the surgeon to remove tumours when otherwise he would not have known where they were?—He does not always distinguish himself in that direction. The results of brain and spinal surgery, based on vivisectional experiments, are not to be compared with the results of abdominal surgery.

9097. Based also on vivisectional experiments?—No, the most skilful abdominal surgeon of the Victorian era, Lawson Tait, publicly foreswore any alliance or allegiance that he had to knowledge vivisectionally obtained. And the first ovariotomy done in England was not done on an animal, but on a human being.

9098. I understand, then, on the whole, that although you do not think that experiments on animals have advanced our knowledge in a useful direction very largely, still you do think that they have been useful to a certain extent?—They have advanced, without doubt, our diagnostic knowledge.

9099. Therefore, you would not be inclined entirely to abolish such experimentation?—I have already said that, on the whole, what I am inclined to is a considerable restriction of vivisectional investigations.

9100. (*Dr. Wilson.*) Reference has been made to experimental work in physiology. Would you be in favour of the illustration of physiological lectures by experimentation on animals?—I am afraid that is a moot point, upon which I have not made up my mind. I have had no actual practical experience of physiological teaching, and I should be sorry to commit myself definitely on that problem.

9101. (*Chairman.*) There is just one question I should like to ask you. You said that if the homœopaths had had laboratories and sufficient funds for carrying on investigations, they might have made as many discoveries as have been made in other laboratories where experiments on animals are conducted. What would be the nature of the experiments, on the principles that you have spoken of, in such a laboratory?—Experiments on human beings and the physical examination, so far as practicable, of the various system and organs of the human beings while the experiments are going on.

9102. You would not want laboratories for that, would you?—You want a laboratory for examining the blood, the urine, the perspirations, excreta, and so on.

9103. That is a very simple thing; that would be more in the nature of a consulting room?—No, the blood examinations made nowadays are most complicated and expensive businesses.

9104. I did not understand what you meant by saying that laboratories were required for your homeopathic investigations; but I see now what you mean?—They would have to be as extensive and as well equipped as those in use in the present day.

TWENTY-FIRST DAY.

Wednesday, 5th June 1907.

PRESENT:

The Right Hon. The Viscount Selby (*Chairman*).

Colonel the Right Hon. A. M. Lockwood, C.V.O., M.P.
Sir W. S. Church, Bart., K.C.B., M.D.
Sir W. J. Collins, M.P., M.D., F.R.C.S.
Sir M. D. Chalmers, K.C.B., C.S.I.
Mr. A. J. Ram, K.C.
Mr. W. H. Gaskell, M.D., F.R.S.
Mr. J. Tomkinson, M.P.
Mr. G. Wilson, LL.D., M.D.

Captain C. Bigham, C.M.G. (*Secretary*).

Miss L. Lind-af-Hageby, recalled; and further Examined.

Miss L. Lind-af-Hageby

5 June 1907.

9105. (*Sir Mackenzie Chalmers.*) I want to ask you a few questions, please. I think you described yourself, in answer to one question, as a lecturer and writer?—Yes.

9106. Do you lecture and write on any subject besides vivisection?—I have written and lectured on a great many subjects—social, educational, and literary subjects. My articles have generally appeared in the Swedish press and magazines.

9107. In England are you working chiefly for anti-vivisection?—For the last five years I have exclusively worked for anti-vivisection.

9108. For the last five years you have given yourself up to it?—Yes, for seven years I have been most keenly interested in it, but for the last five years I have given myself exclusively to it.

9109. As I understand, you do that as a labour of love and without remuneration?—Yes.

9110. Who publishes your books, are they done by yourself or a society?—If you mean my books on vivisection, I have only written one book, "The Shambles of Science."

9111. Only that one?—Only that one, together with Miss Schartau; it was first published by Mr. Ernest Bell. After the trial, when Mr. Bell withdrew it, it was brought out by Miss Schartau and myself.

9112. As publishers?—As publishers.

9113. Not by any society?—No.

9114. Have you seen any experiments, except lecture experiments? Have you seen any research experiments?—No, I have not seen any research experiments, except, perhaps, after demonstrations before students. Sometimes it happened that one or two physiologists remained, and that some special inquiry was settled by one or two experiments.

9115. But everything you have seen yourself has been in connection with physiological lectures?—With physiological demonstrations. I have visited some physiological laboratories, and seen the effects of research experiments, if I may put it in that way.

9116. You have seen the animals afterwards?—Yes.

9117. Have you ever found any of those animals suffering?—At the Pasteur Institute I have found animals suffering.

9118. But there they are experimenting on rabies and other matters?—They carry on very many experiments of all kinds.

9119. I was asking about England. Have you visited any physiological laboratories in England, and seen the animals afterwards?—I have visited the Brown Institute, where I saw a number of fox terriers intended

for experiment, and I was not very pleased with the way they were kept. I did not consider it very humane. But I have not seen any animals after they have been used for private research.

9120. May I ask how many actual experiments you have seen in England?—We considered in 1903, when we counted over 100 lectures that we had attended, that we had seen demonstrations at about 50.

9121. Where were those lectures, please?—Some lectures were at the Imperial Institute, among them a course of lectures by Dr. Pembrey on animal heat. At the same Institute another course of lectures on the sources of animal energy by Professor Starling; on the circulation by Dr. Brodie; and on the chemistry of muscle and nerve by Professor Halliburton; on the action of anæsthetics and narcotics by Dr. A. D. Waller. Those at University College were on the mechanism of the secretory process by Dr. Bayliss; those at King's College on pancreatic secretion by Professor Starling; and on co-ordination by Dr. F. W. Mott. Then we attended all Dr. Brodie's lectures at the London School of Medicine for Women.

9122. You have kindly given us the names of the demonstrators?—I have given them now.

9123. The only one, I think, whom we have had before us is Professor Starling. Have you read his evidence?—Yes, I have.

9124. Do you agree with it?—I am afraid I do not.

9125. At the time you attended these lectures, may I ask whether you went simply to see what would happen, or whether you went having already made up your mind that vivisection was wrong and cruel?—I, of course, had made up my mind, as I think I explained to Lord Selby, in answer to one of the first questions put to me; but at the same time, I was honestly open to conviction—both Miss Schartau and I were. We started attending these lectures with a sort of idea that anti-vivisectors had exaggerated, and we did not start attending these lectures with any fixed idea to write a book or to come out with a public accusation.

9126. That is what I wanted to know, rather?—No, not at all; and, if we had, perhaps sometimes we should have observed details more than we did. I have noticed in reading through my notes, how clear it is that there was no such intention at all at first. It was only after considerable experience that we felt we would like to write about it.

9127. May I put it in this way. If you had not found what you thought was a certain amount of horrors, would you have been disappointed?—No, we should have been very glad.

9128. In the case of all these experiments the animal according to law, had to be anæsthetised?—Yes.

9129. And it had to be killed before it recovered?—Yes.

9130. In your opinion in how many cases was the anæsthetic insufficient?—That question could best be answered by a reference to the "Shambles of Science." I could not at this moment say how many experiments are described there, but I have already pointed out that there are two which describe the efforts to produce complete anæsthesia, especially "A Grand Demonstration," described at the end of the book.

9131. We will come to that presently; but in two cases specially you thought that the animal was not properly anæsthetised?—I should not say that. In two cases we thought efforts were made to produce complete anæsthesia, and those cases are recorded faithfully in the book. In the majority of cases we did not get that impression, and that is also recorded in the "Shambles of Science."

9132. Have you made any independent study on anæsthetics?—I had previously attended Dr. Waller's course of lectures on the action of anæsthetics and narcotics in order to get efficiency on that subject. I have just heard—I heard it before the Commission the last time—that he is considered a great authority on the subject. I have also attended operations on human beings and seen their administration.

9133. You have seen many operations on human beings?—Yes. I have also had chloroform myself and other anæsthetics.

9134. Perhaps I may ask you when you had chloroform yourself were you conscious?—No, I was not.

9135. You felt no pain?—No, I felt no pain.

9136. Have you seen the evidence of Mr. Morris, the President of the Royal College of Surgeons?—I have read it through, but rather carelessly.

9137. I merely wanted to ask you generally. What he told us was that when an anæsthetic is given, the power of feeling pain disappears before the power of motion; and he was talking of a long experience as a surgeon on human beings. Do you agree with that?—I do not think that is always so. I think there are cases, and I have here an extract from Professor Flint, who is an authority, to that effect in his "Handbook of Physiology," showing that a patient may actually feel the operation under light anæsthesia, and yet at the time of regaining consciousness perfectly may forget that he has felt the pain. He says, "Voluntary movements and cries are observed in persons subjected to painful surgical operations, when incompletely under the influence of an anæsthetic, concerning the character of which there can be no doubt. The movements are voluntary, and the cries are evidence of the acute perception of pain, but such patients have no recollection of any painful sensation. So far as can be judged from what is known of the encephalic centres, the pain under these conditions is perceived by some nerve-centre, probably in the pons varolii, but the impression is not conveyed to the cerebrum, and is not recorded by the memory" (p. 578). That is his view.

9138. That raises the point whether there is really pain in a sentient animal or only what you may call a local feeling of pain?—This would be a sensation of pain at the time, though the brain is unable to record it afterwards, to remember it. I have felt the same once myself, when I had nitrous oxide. I had had a tooth taken out some years previously by an incompetent dentist, and I had 11 tiny pieces left in my jaw which had to be extracted afterwards. I felt all the pain in a sort of way whilst this was being done, but when I recovered I had a faint recollection only that I had felt pain, and had heard what the dentist and anæsthetist said.

9139. Then your brain was not under complete anæsthesia?—It was partly.

9140. Mr. Morris's evidence was to this effect, that you might have a person really, as he believed, completely anæsthetised, but that in certain operations, especially touching certain nerves, you might have movements and cries and yet no pain?—That is said, I should think, not only by Mr. Morris, but it has been said by a number of surgeons. The testimony is always that the patient does not remember anything afterwards; but I think I have answered that, in giving my point of view, and in quoting Professor Flint's opinion. But I think that all anæsthetists are agreed that in perfect anæsthesia the body should be limp and motionless.

9141. Would you depend upon the nature of the anæsthetic used or not?—No, I do not think so. I presume that we are talking of ether and chloroform now.

9142. Or an overdose of morphia would have the same effect?—I do not think an overdose of morphia can be classed in the same category with an anæsthetic.

9143. Then you rather disagree with some scientific evidence which we have had?—Yes, I think I do.

9144. Then Mr. Morris further went on to say that to some extent consciousness and certainly power of movement came back before sensitiveness to pain. Would you agree with that?—I do not agree that that is always the case. I have a good deal of evidence which could be brought to show that that is not always the case. It may be the case, but not always.

9145. What I was coming to really is this: In certain animals you observed, as you have said, that there were movements which looked like the movements of an animal in suffering, from which you inferred that the animals were suffering?—Yes.

9146. Do not you think it is possible that those were merely reflex movements; that you may have cries and you may have movements without any real suffering?—I do not think so. I think those cases were cases of returning consciousness. At all events, it is not an ideal condition that the animal should move or cry; and as we can only go by signs, nobody can say, except by signs, whether the animal or person is suffering pain.

9147. Do you agree or not with some evidence we have had that in cutting certain nerves you always get a nervous contraction, although the animal is

Miss L. Lindaf-Hageby.

5 June 1907.

absolutely under anæsthesia?—Yes, you may get a nervous contraction; but that is quite different from the purposive movement which I have seen in some animals, notably in the so-called "brown dog," or the movements that I saw in the dog that I described under the title of the "Troublesome Dog." That is not a mere nerve contraction.

9148. Now I want to ask you, generally, have you seen Dr. Thane's observations on your book?—I have now.

9149. Having read them, do you still adhere to your statements, or do you agree to an extent with Dr. Thane?—I still adhere altogether to my statements in "Shambles of Science." I think Dr. Thane's criticism touches minor points, but leaves the book on the whole very much untouched.

9150. In what respect does it leave it untouched—generally, I mean to say. You say that it touches on some minor points?—For instance, he says: "The accounts given of the proceedings themselves are generally fairly correct."

9151. Yes; it is the inferences which you draw that I think he objects to?—Yes, I suppose he does.

9152. Which, he says, are not justified by the facts observed—that is his point?—He says: "The accounts given of the proceedings themselves are generally fairly correct."

9153. But that you misinterpreted what you saw?—He objects to the "tone" in which the work is written, and to the suggestion of "dishonesty and dishonourable conduct."

9154. Do you really say that there was dishonesty and dishonourable conduct in what you saw among the lecturers there?—I would not define it as "dishonest." I do not think that word is used throughout the book—or "dishonourable conduct."

9155. Do not you think that these men who were experimenting every day are capable of administering an anæsthetic properly?—I cannot pronounce an opinion as to whether they were capable or not. I can only speak to what I saw; that I did not think they did produce proper anæsthesia.

9156. Did you ever point out to any demonstrators at the time that the animal was not properly under anæsthesia?—No, I did not.

9157. Do not you think it would have been fairer, if you thought that the animal had been suffering, to call the experimenter's attention to it, and say: "Now, I saw movements which I thought indicated consciousness"?—I had experience of what happened when that was done once. There was a cat struggling very much at one of Dr. Bayliss's lectures, and a girl who was there said: "I am sure they have forgotten to give an anæsthetic." She told a student, a man, to go out and tell the lecturer that he had forgotten to anæsthetise this animal; and I am very pleased to see that Dr. Thane does not deny that this cat moved on the operating board before the lecture, or that Dr. Bayliss was fetched in consequence—it is in "The Struggling Cat."

9158. Where does Dr. Thane say that?—In his observations on "The Struggling Cat," page 6. Dr. Bayliss has evidently acknowledged that the cat began to move when he had gone out of the room to get his notes. Then, of course, his account is different from ours. He says that he came in and turned a tap.

9159. Yes?—Whereas we say that he came in and tightened the strings, and went out again, smoking his pipe, I believe—there is no objection to his smoking his pipe.

9160. Did he not also turn a tap?—No.

9161. Are you sure?—I am positive that he did not turn a tap.

9162. You know how the anæsthetic is administered there—from another room?—Yes?

9163. You know that the bottle is in another room?—Yes?

9164. With a pipe underneath the floor?—Yes. That is not the argument on this occasion. Dr. Bayliss says there was natural respiration. He admits that upon this occasion there was no artificial respiration, and consequently the anæsthetic could not come from another room. He says: "The anæsthetic was given from a Woulff's bottle with natural respiration." That would be quite a different sort of apparatus, and we did not see a Woulff's bottle (I know a Woulff's bottle quite well) upon that occasion, nor did we see Dr. Bayliss turn any tap. Moreover, the cat was placed in the corner of the room when we came in, on its little operating board, and afterwards it was moved on to the large table or counter before the students, and there was no bottle or anæsthetising apparatus moved with it.

9165. When the cat began to move, do you think there was any consciousness, or was it simply the reflex movements before returning consciousness came on?—I should say that it was entirely conscious. Dr. Bayliss says it moved; he does not deny that it moved.

9166. You think that that cat never had any anæsthetic?—Dr. Bayliss acknowledged later on that he had been experimenting on this cat earlier in the afternoon—that cat had been there a long time—and then he had gone out. And even supposing there had been the apparatus there, the cat was lying there all alone, and nobody attending to it. I think that is a strong point.

9167. It depends upon the nature of the apparatus. In some of these laboratories there is an automatic apparatus?—But Dr. Bayliss says it was not an automatic apparatus on this occasion. He says there was natural respiration.

9168. May I just read to you what Dr. Thane says, and ask you if you agree?—Yes.

9169. "This was an experiment on the production of heat in the sub-maxillary gland. The anæsthetic was being given from a Woulff's bottle with natural respiration. The lecturer left the theatre to get his notes." How long was he away?—I cannot say, because when we came into the room there was no lecturer there. I think we came first of all the students. There was only the struggling cat when we went into the room, and it was struggling very much when——

9170. "The cat began to move"?—Yes, Dr. Bayliss says "the cat began to move," but as Dr. Bayliss was not there when we entered, and as he acknowledges that he was not there when we entered, he cannot possibly know how much or how little that cat moved.

9171. But he can know how long he was away?—Yes, but he cannot know the amount of the struggles.

9172. "A student fetched him, and he come at once, and gave more anæsthetic"?—Yes, he came in, but I do not agree that he gave more anæsthetic.

9173. Have you made any inquiry from him about it?—Naturally not.

9174. "This required only the turning of a tap; possibly the reporter mistook the turning of the tap for tightening the strings"?—It is very strange. I cannot understand how it would be possible with natural respiration to produce more anæsthesia merely by turning a tap. It would be possible with artificial respiration when the air is being pumped continually from a pump by turning a tap. It is altogether beyond me, and I cannot find any explanation of such a thing.

9175. (*Colonel Lockwood.*) He gives the explanation Question 1767, in answer to Mr. Tomkinson?—Yes, I understand that it is possible with artificial respiration, but not with natural respiration.

9176. (*Dr. Wilson.*) Was there a tube in the trachea?—No, there was no tube in the trachea.

9177. (*Sir Mackenzie Chalmers.*) There was no tube in the trachea?—No.

9178. How was the anæsthetic applied in this case?—I saw no anæsthetic applied, so that I could not answer that question. Whether Dr. Bayliss had applied an anæsthetic to that animal before we came into the room I cannot say, but I do speak to this: That when we came in, and it was struggling in a corner of the room, there was no anæsthetic applied.

9179. Was Dr. Bayliss examined at the trial? Was that one of the cases at the trial?—No, that case was never touched upon.

9180. Then Dr. Bayliss says: "I see that the lady student, who is reported as saying, 'I am sure they have forgotten to give the cat an anæsthetic' has been advertised for. I have not heard whether she has been found"?—I do not know who advertised for her. I did not advertise for her.

9181. She was a stranger to you?—Yes.

9182. (*Chairman.*) Did I correctly understand you to say, in answer to a previous question, that you had never spoken to the lecturer, and that that was in

consequence, more or less, of what had happened when a lady student had spoken to him?—Yes, I saw the effect.

9183. What happened to the lady student?

9184. (*Sir Mackenzie Chalmers.*) She seems to have fetched Dr. Bayliss?—She sent for Dr. Bayliss. I meant to infer that it had very little effect that Dr. Bayliss knew of the distress of the young girl, who seemed very sensitive; in fact, she began to cry.

9185. (*Chairman.*) I thought the suggestion was that Dr. Bayliss treated her in some way that was extremely discouraging by his manner?—No, I simply meant that he took very little notice of it.

9186. (*Sir Mackenzie Chalmers.*) Are we to take it from you that your impression is that that cat, instead of having more anæsthetic given to it when it began to move, was simply tied down tighter?—That was my impression.

9187. That we must inquire into. After the experimenter's attention had been called to the fact, after somebody had gone out and told him that the cat was moving, instead of increasing or giving any anæsthetic, he merely tied down the cat more tightly?—He pulled the strings at the four corners and tightened them.

9188. What happened after that?—The cat was lying on its back.

9189. What happened after that to that cat?—After that the lecture began. Dr. Bayliss came in and explained that they were rather short of dogs in the laboratory, and this afternoon he could not have a dog. He also said that he had experimented on this cat earlier in the afternoon. We were sitting behind this girl who had shown so much distress, and we saw that it distressed her still further. She was then spoken to by a lady student at University College, who made light of it. I cannot recollect what actually was said, but she laughed, and probably reassured the girl that the cat was not suffering.

9190. How long did the lecture continue?—The lecture continued, I suppose, an hour and ten minutes—a little more.

9191. Was the cat killed at the end of the lecture?—No.

9192. No?—No, the cat was taken out before the hour was over.

9193. You do not know what happened to it?—No.

9194. Did the cat again make any motion; was there any sign of pain that you saw in the cat after what was done to it?—Yes, the cat struggled.

9195. Struggled still?—Struggled throughout the time we saw it; but, as often happens when you see an animal struggling, it did not show the same forcible movements—movements of the same strength—as it did at the beginning, which accounted for the girl who was so distressed becoming more calm afterwards. But it did move all the time distinctly.

9196. How far were you off?—I was very near; I was always very near. And Miss Schartau and I always walked up to the animal before leaving whenever the animal was not taken out before the lecture was over, and looked at it. Sometimes we spoke to the laboratory attendant.

9197. There we have an issue of facts which we must inquire into.

9198. (*Sir William Collins.*) Was Dr. Thane present at any of these experiments?—No, he was not.

9199. (*Sir Mackenzie Chalmers.*) Anyone can go in, I suppose; anyone about the place?—I think any medical man is allowed to go in.

9200. There are some other points which I dare say other members of the Commission will ask you about the investigation made by Dr. Thane. I want to ask you, generally, do you object to all experiments on animals? How far do you go in that?—Yes, I object to all experiments on animals.

9201. Irrespective of whether pain is caused or not?—I do not believe that vivisection can be made painless.

9202. You do not believe in complete anæsthesia. I want to take you to this case first. Supposing that an animal is properly anæsthetised, and is killed before the experiment concludes, before the anæsthesia passes off, do you object to that?—Supposing an animal could be properly anæsthetised, which I deny for vivisection operations as a rule, but supposing it could be, and supposing it were killed before it recovers consciousness, I should not object to that as an anti-vivisectionist; but I should object to it as a general humanitarian and for other reasons, but not merely as an anti-vivisectionist.

Miss L. Lind-af-Hageby.

5 June 1907.

9203. You do not object that the animals should be killed when they are unnecessary or for various reasons when they are a nuisance?—I object to the sacrifice of life.

9204. May I ask you this, for instance? You know that 20,000 dogs are killed every year in the Dogs' Home in London?—Yes.

9205. What I may call superfluous dogs?—Yes?

9206. Do you object to that?—Under present circumstances, and as the world is, I think it is a regrettable necessity, and as vivisection exists it is far better for the dogs to be protected and killed in that painless way. But I do not agree with what Professor Starling said before this Commission, that this is done to rid the streets of "the danger of stray dogs." I think it is done from a humane point of view.

9207. I want to know whether you object to that or not?—No, not at present.

9208. Then if a dog which had to be destroyed could be properly anæsthetised, do you think there would be any objection to increasing knowledge by means of its death?—I should think there is. Because I know that vivisection anæsthesia is always unreliable. I would trust a veterinary surgeon of skill and capacity to operate on an animal painlessly if he sought to do so; but I would never trust a vivisector in that capacity. Moreover, it must be remembered that vivisection is not only a few experiments on so-called "anæsthetised" animals.

9209. I will take you to the others afterwards. I want, first of all, to know whether you think it is wrong and objectionable, where an animal is to be killed, and assuming that you can give it complete anæsthesia, to use it for experimental purposes?—Yes; for the reasons I have stated.

9210. Then what it comes to is this: That you would not trust any lecturer who performs experiments, or any scientific man, to give complete anæsthesia?—No, from my knowledge of what vivisection is I cannot trust vivisectors with regard to complete anæsthesia.

9211. You do not agree with the experimenters when they say that in the case of an animal they give much heavier doses of anæsthetic than they would in the case of a human being, because it is somewhat important that the human being should recover from the operation?—I brought evidence last time to show that that is not so. I brought a considerable amount of evidence with regard to light anæsthesia to contradict that entirely, and also to show that fatal doses are not generally employed.

9212. Your opinion is that people who are performing what I may call vivisectional experiments prefer light anæsthesia, and do not give complete anæsthesia?—Yes; and in some cases they prefer no anæsthesia at all.

9213. Can you give me any case of that?—I said last time that I could give the Commission a considerable number.

9214. I have it all before me in your evidence. Can you give me any case in England?—There is a statement in a book that I referred to by Sir Lauder Brunton, saying that experiments with drugs cannot be made under anæsthesia.

9215. I have not come to those yet; those are what you may call feeding experiments?—Drug experiments, poison experiments; they cannot be made under anæsthetics, because the anæsthetic would interfere with the result.

9216. I quite agree with that. I want to ask you this. How far does your objection go on moral grounds to vaccination, the using of calves for the preparation of vaccine?—I object to vaccination for the sake both of the infant and of the calf.

9217. Have you ever seen a bad case of smallpox?—No, I have not.

9218. It is a pleasure some of us have had?—I have seen scars.

9219. I may take it therefore that if you object to vaccination you object to the whole principle of what

Miss L. Lindaf-Hageby.

5 June 1907.

is called serum therapy?—I do, both on humanitarian and on hygienic grounds.

9220. We have had a good deal of evidence about the case of diphtheria. You have been in hospitals and seen children dying of diphtheria, have you not?—I have, and I had diphtheria myself some years ago, very severely; I did not have the serum, and I recovered perfectly; whilst a friend of mine did have the serum, and got several complications, which taught me an object lesson.

9221. Are you not generalising too much from a single case?—I think not. I have plenty of evidence before me of very serious complications following on the use of the antitoxin. I have also a German book, written only for the medical profession, which gives no less than 13 diseases as the result of the use of diphtheria antitoxin. It is not an ideal remedy.

9222. No, I do not suppose that any remedy is ideal. But if there is a great concurrence of medical opinion that life is saved by using antitoxin in many cases in which it would be lost without, do you think it is unjustifiable to use it?—There is a considerable amount of medical opinion against the use of anti-toxin, both in this country and in others; I could quote many names; but even supposing that the majority of the medical profession claim that diphtheria anti-toxin is an invaluable remedy, that does not prove that it really is so. Medical history is full of discarded theories and superstitions that have gone. I have brought quotations from three works on medical history, but I will not trouble the Commission with them, in which it is specially emphasised that medical history is not least interesting because it always teaches you what not to do.

9223. I take it, then, that you object absolutely to the use of antitoxin?—Yes.

9224. If you were convinced that it was useful, would you still think it wrong?—I would, because I know from personal experience, from having had diphtheria, that there are other means of fighting the disease more natural and followed by less objectionable results.

9225. We had some very interesting evidence the other day about snake bite, and I want to ask you this. Do you think it is right to use animals in order to experiment on a new remedy for snake bite?—I should think it would be better to use other means. I do not believe in the scientific value of these experiments.

9226. Did you look at Colonel Rogers's evidence of the other day; have you seen it?—I am afraid I have not read it very carefully.

9227. What he told us was that he is able now to save a good many lives of people or animals who have been bitten by snakes, by scarifying the point and putting in permanganate of potash, and that he discovered that by a series of experiments, on, say, 20 or 30 unfortunate animals, it may have the effect of saving many hundreds of human lives and animal lives. Do you think it is justifiable or not?—There is no harm in using the remedy itself.

9228. Do you think he was justified in using animals to experiment on?—I think it would be better if he had used himself.

9229. The poor man has not got 20 or 30 lives. I am afraid he would have died 20 or 30 times. However, that is your answer. You think he ought not to have used animals?—Yes, I think, as in the case of other people who are devoted to either scientific or social or ideal questions of any kind, we all know that the highest thing is to sacrifice yourself, not others.

9230. Do you suggest that all experiments should be made first on the experimentor?—Certainly. I have no objection to vivisection, provided that the vivisectors experiment on themselves, and nobody could have. They are perfectly entitled to their opinions.

9231. A good many experiments have been tried by doctors on themselves?—A very small percentage of the whole.

9232. Do you draw any distinction yourself between causing pain to an animal in sport, and causing pain to an animal with the object of finding cures?—Certainly. I object to what is called blood sports, most seriously.

9233. All sports?—And I consider the anti-vivisectionist who does not object to them most illogical. I consider the anti-vivisectionist who takes pleasure in blood sports, which cause pain to animals, most illogical. In that view I believe I am not supported by the total number of anti-vivisectionists; but that is my opinion.

9234. I only wanted to know how far you go. Take, for instance, this case. Have you ever seen a good day's rabbit shooting?—No, but I can imagine what it is. I should think it hateful.

9235. But in what I may call your public agitation you do not include sports?—There must be a division of labour for everybody. I am a thorough humanitarian, so far as I can possibly be so. I have written against sport a good deal in Sweden.

9236. I do not know whether it is fair to ask you, which do you think is the most wrong: in rabbit shooting, to maim an unfortunate rabbit which crawls into a hole to die, or to perform an experiment on a rabbit which you think and hope may result in benefit to human beings?—That all depends on the way in which the two actions are done. My personal opinion would be that the vivisector (though I am a very strong anti-vivisectionist) who honestly thinks he works for the good of humanity, or the good of science, and who honestly tries to render his experiments painless, is on a higher moral scale than the man who seeks his pleasure from maiming and hurting animals.

9237. His pleasure is not in maiming and hurting; but in the pursuit of his pleasure it is incidental?—That alters the case a little; it depends on how far he is conscious of the maiming and hurting of animals, of course.

9238. (*Chairman.*) It is wicked in a bad shot, and not wicked in a good shot, you mean?—I do not mean exactly that. It depends very much upon the man's attitude of mind, does it not?

9239. (*Sir Mackenzie Chalmers.*) You agree that new remedies and new drugs must be tried, do you not?—Yes; but I think that the development of medicine is rather the decline of drugging; I think that is one of the signs of the time.

9240. You think, if I may say so, that it is wasted labour to try new remedies and new drugs?—I think it would be far better if we turned our attention to the preservation of health, and in a minor way to the prevention of disease, by strengthening the general health.

9241. So that you do not think it is justifiable, if a new remedy is brought in, to try it first on an animal, and then on a human being?—No, especially as experiments on animals are so useless. Professor Starling has told this Commission that "the final experiment must always be on man," and we have many statements against the danger of applying the results of experiments on the lower animals directly in the sick room.

9242. I may take it that you object to every experiment of every sort or kind for the purpose of advancing knowledge, believing that it is both wrong and useless?—Yes. There are experiments, of course, which I might quote which are altogether different from the ordinary experiments which are performed now. There is, for instance, one experiment given in Beddard's "Practical Physiology" (p. 151), with the object of studying the intestinal movements in a live cat under the Röntgen Rays. The cat is taken gently, it is not even anæsthetised, there is not even that discomfort to the cat, the movements of the intestines are studied by means of the Röntgen Rays, and it is specially said that the cat must be treated gently, as otherwise abnormal conditions will be set up. Nobody can object to an experiment of that kind, either on a human being or an animal. There is a certain class of physiological apparatus which is being used nowadays for experiments on human beings, by physiologists on themselves, and those experiments are not at all objectionable. I have brought plenty of pictures of that kind of apparatus, if the Commission care to see them. Now you can study the pulse, the blood pressure, and a great many physiological questions by means of this new physiological apparatus for man. And that is developing every day; and I believe that if humanitarian pressure is strong enough, physiologists will more and more have to apply this painless kind of apparatus to experiments on animals as well as on human beings.

9243. I take it that the general object of your evidence is that experiments on animals should be disallowed by law?—Yes.

9244. Without exception?—Yes.

9245. Assuming that that cannot be done, have you any suggestions to make as to how the existing law should be modified in any way?—I have. I would first of all suggest that demonstration experiments before students should be forbidden. Both in the "Shambles of Science," and later, in Sir Thornley Stoker's evidence before this Commission, it has been brought out very strongly that such experiments are demoralising; and, after my recent debate with Professor Halliburton a few days ago, where students came in large numbers, and behaved, as the Press characterised it, in a very brutal way, I feel still more strongly that those experiments ought to be discontinued.

9246. Have you any other suggestions to make?—Yes; that the use of morphia should be made illegal as an anæsthetic.

9247. (*Mr. Tomkinson.*) And curare?—Curare should be forbidden altogether.

9248. (*Sir Mackenzie Chalmers.*) Curare should be forbidden altogether?—Yes.

9249. And morphia should be forbidden as an anæsthetic?—Yes.

9250. You do not object to morphia being given previously to an anæsthetic?—No, not to help the induction of anæsthesia simply. But I believe when morphia is given in a fairly large dose it produces a condition which is deceptive, and that therefore, when vivisectors give a very small dose of a real anæsthetic afterwards, it may be misleading, but I do not think that that could be legislated against. But nobody can object to the use of morphia merely as an induction to anæsthesia.

9251. Have you any other suggestions to make?—Yes; that experiments on all the higher animals, dogs, cats, monkeys, horses, asses, etc., should be forbidden.

9252. With the exception of man, you think all other animals should be excluded?—I do not approve of experiments on men and women, except voluntary ones, and of those only when undertaken for the real good of the men and women—the patients; of course, all life is an experiment, if you extend the word.

9253. I do not want to play with words. Every dose of medicine is an experiment, I suppose?—Yes.

9254. Have you any other suggestion to make?—My whole object is that the Act should be repealed.

9255. Assuming that that is not possible, have you thought of any other course?—Yes, I have another suggestion to make, which I brought out last time, and which I feel very strongly about; that is, that students should not be allowed to experiment on frogs.

9256. Even pithed frogs?—Frogs are now experimented on by unlicensed people.

9257. After death, so to speak?—The question is, what is death? I have not quite finished my evidence on that yet, if I may be allowed to continue.

9258. You mean, that there are certain modes of pithing which, in your opinion, do not destroy consciousness—the sensation of pain?—I consider that a really pithed frog, in which the brain and spinal cord have been totally destroyed, does not feel pain.

9259. But you think that as long as there is any purposive movement the animal does feel pain?—Yes, as long as the spinal cord is intact.

9260. (*Chairman.*) You wish, I think, to add a note to your evidence with regard to Question 7430?—Yes.

9261. I think you wrote to the Secretary, and he suggested that you had better make it part of your evidence to-day?—Yes.

9262. It relates to the pithing of frogs; and perhaps you will just tell us what it is?—There were two notes, in fact three notes that I sent in, which I was asked to give in evidence instead. I was asked at Question 7315 to give a reference to a passage of Claude Bernard. The words which I quoted from Bernard's "Lecons de Physiologie opératoire," are preceded by the following sentence, relating to the one referred to, which I translate:—"The dose which we generally employ is 5 centigrammes, but one can give the dog, without any danger, a stronger dose, even double, of morphine, provided the salt is pure. The animal still remains sensitive, etc." Then I have a few words, if I may add them, on morphia; in fact, just a few sentences. I wish to add in extension of my evidence on morphia last time that the morphia doses generally recommended in text books are not fatal doses (I have a list of such doses here), and also that the survival of animals experimented upon under morphia is proof positive that the doses given are not always fatal ones. (I have another list of such instances.) Even Professor Starling does not assert in his evidence that all animals die after the so-called fatal doses of morphia to which he refers, but says that in most cases they do so; that was at Questions 3607-8. I have evidence here from Dr. William Murrell's "Manual of Pharmacology and Therapeutics," that even such a strong dose as 37 grains of morphia has been given to a dog without affecting it; and that doses of 17 grains have been given without producing serious symptoms; and Professor Starling mentioned a dose of 15 grains as being the utmost limit of a fatal dose.

Miss L. Lind-af-Hageby.

5 June 1907.

9263. What do you mean by the utmost limit of a fatal dose? If more was given it would be fatal, would it not?—Yes; but Professor Starling mentioned before the Commission that a fatal dose would be within one grain and a half and up to 15 grains. I have several extracts here to show that over 30 grains have been proved not to be fatal doses in dogs.

9264. (*Dr. Gaskell.*) Would you mind giving us the size of the dog?

9265. (*Chairman.*) I did not intend to interrupt the examination on this point; it is another point altogether; you were speaking about pithing frogs?—Yes. I can leave the morphia now until I am asked questions upon it; I have very little more to say about this point.

9266. If you have nearly finished it you might as well continue?—I was asked the size of the dog. This is an extract from a "Manual of Pharmacology and Therapeutics," by William Murrell, Lecturer on Pharmacology and Therapeutics to the Westminster Hospital, Examiner in Materia Medica and Pharmacy to the Conjoint Board of the Royal College of Surgeons and the Royal College of Physicians, London, 1896. Murrell says that "Recent observations show that dogs are but slightly susceptible to the action of morphia. H. C. Wood and David Cerna gave a dog weighing 15½ kilo. a dose of 2·4 gramò (37 grains) of morphin without affecting its respiration. Caldwell gave a dog 17 grains without producing serious symptoms; whilst to a number of other dogs he gave 12 grains hypodermically, with no bad effect" (p. 339). Then Claude Bernard refers to a dose of 30 grains, that is, twice the dose to which Professor Starling refers, and this enormous dose produced great excitement and convulsions of great violence. After four hours the dog was frightened, lay stretched out in a corner, but could walk. The dog was not dead the following day. That is from Claude Bernard's "Leçons sur les Anesthésiques et sur l'Asphyxie" (p. 201).

9267. Without any effect on what, does he say?—He gave this enormous dose. It produced great excitement and convulsions of great violence. "Without effect" was Murrell's quotation, which I quoted before.

9268. Without any effect on what?—On respiration.

9269. It was confined to that?—In both quotations it is shown that the dose was not fatal.

9270. (*Sir William Collins.*) Did the dog recover?—The dog recovered—both dogs recovered.

9271. (*Mr. Tomkinson.*) The dog did not lose consciousness?—Not in these two cases. Shall I go on to the next note that I have?

9272. (*Chairman.*) Yes, please; that is about the frog?—Yes. At Question 7430 I was asked to supply a note of the physiologists who attach different meanings to the word "pith." Thorough pithing of a frog is described in the following way by Dr. Augustus D. Waller in his "Exercises in Practical Physiology," part III., page 44: "Insert one blade of a strong pair of scissors into the mouth, as far back as it will go, and cut off the top of the head. . . . . Thoroughly destroy the brain, bulb, and cord by means of a stout wire pushed several times down the spinal canal. The frog is now thoroughly pithed, and should remain permanently flaccid and motionless; any movements of the limbs signify that the spinal cord has not been thoroughly destroyed." In "Essentials of Experimental Physiology," Dr. Brodie gives directions for thorough pithing, on page 16, as well as advice for incomplete pithing on pages 49 and 214. Professor Stirling includes mere decerebration as well as destruction of the brain and spinal cord, under the word "pith" (pages 219, 377, "Outlines of Practical Physiology"). In "Practical Physiology," by Beddard, Edkins, Hill, etc., the word "pith" is used in its proper and inclusive sense (page 14). Professor Busch says under the head-

Miss L. Lind af-Hageby.

5 June 1907.

ing: "Pith a frog. This ordinarily means destroy the brain" (Laboratory Manual of Physiology, page 10). In his evidence before this Commission Professor Starling speaks of a brainless frog as a "pithed frog" (3467), and in the pamphlet, with which I have been favoured, Dr. Thane commits the same error. In the above-mentioned book, Dr. Waller states that "For certain experiments it is necessary only to decerebrate the frog—*i.e.*, to destroy only the hemispheres, or the hemispheres and optic lobes. In this case the scissor cut must not be made quite so far back, and the brain carefully removed." That ends my note on that question. May I ask a question? I have also added a list of those experiments which are recommended in text books to be made on only decerebrated frogs, but if the Commission do not wish to hear it——

9273. I think we had better go on with the examination now; I interrupted you before?—I was asked to give another reference.

9274. If it is only a reference, you might as well give it now?—I have a little comment upon it; so perhaps it had better wait.

9275. (*Mr. Ram.*) Will you tell me, please, what is your attitude with regard to the Act that we are acting under to-day? Would you entirely repeal it?—I would repeal it and substitute another Act prohibiting vivisection. I would not only repeal it ——

9276. You would enact in lieu of it an Act saying that vivisection was to be wholly illegal?—Yes.

9277. How would you define vivisection?—I would define vivisection as experiments calculated to inflict pain on living animals for scientific purposes.

9278. You would limit it to scientific purposes?—I should like to prohibit all painful experiments, scientific and otherwise; but if we are only dealing with scientific vivisection, I dare say it would have to have the word scientific.

9279. Would that not leave a very wide field open by which great pain could be inflicted on a large number of animals, not for scientific purposes, but for purposes which might be considered less worthy than scientific purposes?—Certainly, there is a great deal of other cruelty which should be stopped by other Acts, if possible.

9280. Would you stop all of it?—Personally, I would stop by legal enactment as much as possible, but I have not the slightest hope that in my lifetime all such cruelties will be stopped.

9281. Take the farmyard operations, which have been spoken to by other witnesses; would you stop them?—I think that it should at least be enacted by law that those farmyard operations are not permissible without anæsthetics.

9282. You would give anæsthetics in every case?—Yes.

9283. Every colt, every lamb, and every young animal of every sort?—I think it is most cruel to perform that operation without anæsthetics.

9284. And you would make it illegal to perform any one of those operations on any animal, at any age, without anæsthetics?—Yes, certainly.

9285. Meantime, if the Act is to continue, you make the suggestions that you gave to Sir Mackenzie Chalmers just now?—Yes.

9286. And you do not wish to add to them?—No.

9287. Do you know the practice in America?—I know something of the practice in America.

9288. Do you know that there is no restriction by law there of vivisection?—I know, nor is there in my own country, Sweden, or in Germany or France; and I know something of what is being done in those countries.

9289. Are the practices in those countries worse than they are here to-day?—I consider that they are. I consider that they are much worse in countries where every medical student has the right to vivisect any animal in whatever way he pleases.

9290. Therefore the Act that we are acting under to-day is of advantage in making things better than they are in countries where there is no such Act?—Certainly, I think so.

9291. Do you know anything of the writings of Dr. Leffingwell, an American doctor?—Yes, I know of him.

9292. I have here a book which was sent to me by Mr. Sydney Trist, of the office of the "Animals' Guardian." Do you know the "Animals' Guardian"?—Yes.

9293. Do you know the people connected with it?—I know some of them.

9294. Are they anti-vivisectionists?—Yes.

9295. They sent me this book, and I find in this book that what this gentleman, Dr. Leffingwell, desires is that there should be in America exactly the same Act as we have in England?—Yes.

9296. You are aware that that is what he desires?—Yes.

9297. Then I need not trouble you, as you know it, with extracts from his book. Do you agree with him that in America, and perhaps in Sweden, to have such an Act as we have would be a very great step in advance?—I quite agree; because here, at least, you have an opportunity of finding out something of what is being done, but you cannot in America or Sweden.

9298. And here, too, if any illegal case is brought to the knowledge of the Home Office proceedings can be taken against a person doing an illegal act?—Yes, it should be so.

9299. And inspectors exist for the purpose of finding out whether there are such illegal practices or not?—Yes, they are supposed to.

9300. In how many of the experiments which you have enumerated in the "Shambles of Science" do you consider the Act had been broken?—I think I have been asked that question before.

9301. If you have answered it before I am sorry I have asked you?—I think I was asked the question this morning.

9302. At any rate, I need not tie you down to ones and twos and threes. You do think that in several of those experiments, if not in all, there have been infringements of the Act?—I think that the Act, as it stands now, admits of a great deal of cruelty. There is no effective control over vivisection as the Act stands to-day.

9303. Whether there is control or not, in your opinion some one or more of these cases were infringements of the Act?—I believe, on the whole, it is possible to do a great many cruel things under the Act.

9304. Did any of these cases that you thought cruel strike you as being infringements of the Act?—That is a question that is rather difficult to settle. If a man performs an experiment under licence or under Certificate C, before students, which licence or certificate lays down that the animal should be anæsthetised, and if he employs an anæsthetic that is no real anæsthetic, or if he gives the anæsthetic in a manner that is not proper and is not conducive to total abolition of consciousness, is that infringing the Act? It comes to that question.

9305. (*Colonel Lockwood.*) Like "The Struggling Cat"?—Yes.

9306. (*Mr. Ram.*) You thought, then, that some, at any rate, of these experiments that you saw were conducted in the way you describe?—Yes.

9307. Did you make any representation to any Inspector or to the Home Office as to any one of these alleged breaches of the law?—No.

9308. Over what period do all these experiments extend?—The experiments described in this book extend, I believe, over a period of six months; I am not quite sure.

9309. And at no period during that time did you make any representation or any complaint?—I made representations, but not to the Home Office or to the Inspector.

9310. You made them, I think, to the public through this book?—Yes; I think we did.

9311. Did you ever apply to the experimenter to know whether you had misunderstood what was done or to ask for any explanation?—No, we did not.

9312. I will deal with one or two of those cases in a moment; but before I come to them I want to ask one or two general questions. I refer first to your answer to Question 7243. The question asked you was, "May I point out that the train of your argument really seems to involve a belief on your part that they intended to suggest that the anæsthesia should be so slight that the animals might be conscious; because

it arose in connection with a question of cruelty?" And your answer is this: "My whole evidence is in connection with cruelty"?—Yes.

9313. I take it that that is your position now?—Yes.

9314. Eliminate cruelty and you would not object to vivisection?—But my point of view is that cruelty cannot be eliminated from vivisection.

9315. But take a hypothetical case. Assuming that cruelty could be eliminated, and that there was and could be no suffering on the part of animals, I take it that you would not object to vivisection?—I have already answered that question, too.

9316. Would you mind answering me?—No, I will answer you in the same way: that supposing such an impossible thing were possible as that vivisection could be made painless—are you quoting drug experiments and inoculation and those things, or are you assuming only a surgical case?

9317. I am assuming for the moment a surgical case?—If it were absolutely painless, if it could be made so, and the animal killed immediately after, so that there was absolutely no return of consciousness, I said that I should not object to it merely as an anti-vivisectionist, but I should object to it from a general humanitarian point of view.

9318. I am afraid I do not quite follow that. You as an anti-vivisectionist would not object because there would be no suffering. Will you clear it up?—It is very difficult to answer a hypothetical question.

9319. I will put a question which is not hypothetical. What is the distinction that you draw between the anti-vivisectionist and the humanitarian?—The anti-vivisectionist may be a person who sees very acutely the cruelty and selfishness in vivisection, but has not yet had his eyes opened to other cruelties in the world which may be just as bad, or nearly as bad.

9320. That is your definition of an anti-vivisectionist?—But the general humanitarian is a person who sees other forms of cruelty and selfishness, and is anxious to remedy them, too.

9321. I do not quite follow the distinction?—As a humanitarian, I should object even to the painless vivisection (supposing vivisection could be made painless) of a dog.

9322. Why?—Because, as I have also said in my previous evidence before this Commission, I am not an anti-vivisectionist solely on the ground of pain; I am an anti-vivisectionist on the ground of objecting to the general exploitation of animals.

9323. That is the reason why I referred you to your evidence in which you said "My whole evidence is in connection with cruelty"?—Yes?

9324. Do you wish to modify that?—That I can easily stand by, because my whole evidence had to do with bringing proof that vivisection cannot be made painless.

9325. Do you wish now to go further, and say that you now object to what you call exploiting animals for any purpose?—I am very anxious to be allowed to stick to my position. My position before this Commission is simply that of an anti-vivisectionist, and I am an anti-vivisectionist because I know that vivisection, including drug experimentation, inoculation experimentation that involves keeping an animal alive for a long time, extirpation of organs, and things of that kind, never can or will be made painless. That is my position here.

9326. I am reminded that you said, in answer to Question 7622, "I should object to an experiment on a living animal, supposing it was unconscious . . . because I take my stand against vivisection, not only and entirely on the ground of pain, but on the broader humanitarian ground of objecting to the general exploitation of animals for our use"?—Yes, and I was asked a good many questions last time as to what I considered to be exploitation of animals.

9327. I do not want in the least to go over ground that you have already covered, or to put anything to you which might be an extension of what you said; but do I take it that in your view any pain inflicted on an animal otherwise than for the animal's good is wrong?—I consider it to be so.

9328. How about breaking a horse to harness?—That may be for the animal's good. I consider that the domestication of animals is distinctly for their good, because it trains their minds and helps their general mental development.

Miss L. Lind-af-Hageby.

5 June 1907.

9329. I understand that it is lawful to break a horse to harness with whip and spur, and so on?—I have read a book by a very famous Norwegian trainer of horses who does not do it with whip and spur, but does it in a most humane way; it is a most interesting book.

9330. I wish it was more universal, but I am confining my question to what takes place to-day?—I think that any cruel training of horses and breaking in of horses is most objectionable, but I do not think that the process need be cruel.

9331. Supposing you take the best process that you can conceive, the horse is ultimately broken in, and you make him drag a carriage or a cab in London, not to an excessive extent, you do not injure the horse by doing it, but you make him drag it about contrary to his wishes. Is that right or wrong?—It depends entirely upon the driver, and on the amount of driving that is done with the horse and the amount of load that the horse has to pull.

9332. If it has a moderate load and is driven for an hour or two and is made to go uphill when it would rather not, and is made to go in a cab when it would rather be in the field, is that right or wrong?—I do not think it is cruel to be made to do what you would rather not do. We are all of us made to do what we would rather not do.

9333. Should you call it exploiting the animal?—No, no more than I consider myself exploited by having to give evidence before this Commission. I do not like doing it.

9334. (*Chairman.*) I think there is a little difference. I do not think you have been compelled to come here; you have come willingly. The horse is compelled to go in a shaft and to be fastened to the pole of an omnibus?—But I am compelled by my own moral feeling with regard to vivisection.

9335. There is a great deal of difference between being compelled by your own moral feeling and being compelled by somebody else?—But a father and mother have to compel their child to do a thing very often both mentally and physically. You would not call that cruelty.

9336. We do not like it applied to us when we grow up.

9337. (*Mr. Ram.*) What I really want to know is your definition of exploiting animals. It would be very helpful to us when you are telling us what view you wish us to take?—I could go on for days telling the Commission what I consider to be exploitation of animals.

9338. (*Chairman.*) Then I am sure Mr. Ram will withdraw the question?—It is too broad, I think.

9339. (*Mr. Ram.*) In mercy to the rest of the Commissioners I will withdraw it. It is a fact, is it not, that in consequence of the exploitation of animals—that is, use being made of animals for the convenience of mankind—thousands of animals lead a very comfortable life which they otherwise would not lead; do you agree?—Some animals lead a very comfortable life, but the majority do not.

9340. Supposing that we did not eat sheep and oxen after they were dead, do you suppose that we should keep them with the utmost comfort for three or four years, feed them in winter, and house them in bad weather?—No, but the journey to the slaughter-house and the present slaughter-house methods are anything but comfortable.

9341. Do you think it is not worth the animal's while to have three or four years of a very happy life because at the end it will be killed by a blow?—I would certainly prefer to be a wild sheep than a domestic sheep.

9342. Supposing that mankind did not exploit animals for their own good—horses, cows, and so on—for use in life and for food after death, how many of those animals do you think we should have in this country?—The supply is generally found in nature to meet the demand, and those who have entered upon this very wide question (and many competent people have done so) have come to the conclusion that supposing we gave up eating sheep and oxen the supply would naturally regulate itself, because at the present moment there is a great deal of artificial breeding. For instance, we do not eat dogs and cats in this

Miss L. Lind-af-Hageby.

5 June 1907.

country, and yet that matter can be managed without our being cemeteries for them.

9343. Do you agree with me that if it were not for the use of these animals a great many of them would not exist, or there would be many thousands fewer?—They would not exist in the same quantity.

9344. Why should a man keep a horse at all if he never uses it?—I have not said that a man may not keep a horse provided that he uses it in a humane way.

9344a. Why should a man keep a herd of oxen unless he meant ultimately to eat them or to sell them to others for food?—He might keep oxen as the peasant in Sweden keeps them, to plough his soil and draw his carts and to work.

9345. Do you think that oxen kept to draw carts and till the soil in this country would not have a worse time of it than if they are kept for four years and then knocked on the head and eaten?—Very probably they would at the present moment. It depends whether we are arguing from the point of view of greater humanity or lesser humanity than exists at the present moment.

9346. I will pass from that. Now I want to come to your answer to Question 7645. I will read the question if you desire it, but it is rather long, and the answer is what I want to deal with?—I know the point.

9347. You say: "I should not dream of denying that that method"—that is, the method of immunising animals for cattle plague—"has been discovered by experimentation on animals; in fact, that is something that we all know; but the point is whether some other method might not have been employed, and could not have been employed with equal advantage. I believe, on the whole, in natural immunity versus artificial immunity, and I am not at all inclined to admit that the principle is a true or right one." Could you tell me what other method you had in your mind then?—As relating to that special case, I believe I had in my mind the method which has been referred to before the Commission of isolation and slaughter; that, I think, in the first instance. And, secondly, I had in my mind an objection to the whole system of immunising by means of sera, the various substances drawn from an artificially diseased animal, which I do not believe in.

9348. Then what you would do would be to isolate and not to attempt to immunise at all?—I do not believe in those methods of immunisation. I believe that they are unhygienic—dangerous—blood poisoning.

9349. And you would substitute for them simple isolation?—I would substitute for them sanitation first, prevention of disease and isolation. I believe immensely in the natural powers of the blood of slaying bacteria, in the so-called bacteriacidal powers of the blood.

9350. You are opposed, then, to the use of any sera at all?—I am, from the hygienic point of view as well as the moral.

9351. Some witnesses have told us, and I want to know whether you agree with them, that they object to the use of sera because it is the importing of a substance from the body of an animal into the body of a human creature; is that your objection?—That would not exactly be my objection. If I am to speak on the subject from the scientific point of view, I object to it because I know that the serum of one animal has the power of destroying the red corpuscles of another animal if the serum be injected into that animal—what is referred to as the globulicidal action of the blood; and that wonderful capacity in one's own blood is a proof that we are not meant to lend and borrow blood from one another, and especially not from different species. I also object to it because all artificial immunity which can possibly be induced by these sera is of very little value compared with that of strengthening these normal and natural powers of the blood which, when we have them, are an absolute protection against bacteria and disease.

9352. Then you do not think that there is some artificial immunity which can be obtained?—In some cases no doubt there is a certain amount of truth underlying the whole system of serum therapy, as, for instance, we know that in the case of measles and certain other diseases if you have an attack you are liable to be protected for a certain time. But I believe that the principle is wrong and its application is wrong.

9353. May we not hope that further experiments, the principle being right, might show a way to applying it more accurately and more beneficially than at present?—I do not think so. There is a paper by Dr. Brodie on "The Immediate Action of an Intravenous Injection of Blood Serum,"* of which I have brought an extract, but I will not trouble the Commission with it, showing from his experiments with serum that serum is by no means an innocuous substance, but is always more or less injurious.

9354. Now one or two questions, please, with regard to some of the other cases alluded to in the "Shambles of Science." At page 37 you deal with the incident of the marmot. You speak of a marmot the spinal cord of which had previously been divided?—Yes, I have a short statement on that marmot, which I brought with me last time, in answer to Mr. Thane's statement on the marmot, and perhaps I am allowed to read it now.

9355. (*Chairman.*) That is just what Mr. Ram is going to elicit from you if you will answer his questions instead of reading your statement.

9356. (*Mr. Ram.*) It may be that my questions will save your reading?—Yes.

9357. You observe that the statement which you make is, "We once saw a marmot the spinal cord of which had previously been divided"?—Yes.

9358. On that Mr. Thane says: "I knew this marmot well. It belonged to Dr. Pembrey, of Guy's Hospital Medical School. I have often seen it. It was never experimented upon, save for having its temperature taken. It is the only marmot that has been shown to physiologists in this country. To the general regret it died a short time since. I have since examined the body. The spinal cord has not been divided." Do you accept that statement of Mr. Thane's?—I have prepared my answer here.

9359. I will not preclude it if it is necessary, but will you just tell me first do you accept that statement of Mr. Thane's?—If I may give it in my own words——

9360. (*Chairman.*) The only difficulty is that we have a little essay read in answer to a question?—It is not an essay.

9361. It looks rather formidable?—No, it is not really.

9362. It means that a great deal is introduced which really is not evidence at all very often; it is information furnished to you by others who are not here?—This is a direct answer to the statement which Mr. Thane made in his evidence on the marmot.

9363. But you never saw the marmot except on this one occasion?—I never saw that marmot, except on this occasion.

9364. I think you had better follow the questions.

9365. (*Mr. Ram.*) If you will just answer my question first, you may find that your statement is not necessary. Do you accept that statement of Mr. Thane's as to this marmot, that it is the only marmot that has been shown to physiologists in this country; that it died, and that he examined the body and found that the spinal cord had not been divided?—Very well. I will answer your question so far as I can. The statement that that marmot had never been experimented upon save for having its temperature taken is altogether incorrect. According to a paper by Dr. M. S. Pembrey——

9366. (*Chairman.*) Now this is the very thing——?—I cannot answer the question unless——

9367. Will you allow me just to say this. We are not here for you to disprove what Dr. Thane may say about this marmot by saying that Dr. Pembrey has said something else. If you think it necessary, Dr. Pembrey could come here. We cannot try the issue as to whether that marmot was experimented upon before or had had its spinal cord severed?—But, my Lord, it is an answer to a personal attack on me, and I understood from what you said last time that I was to be allowed to answer anything which had been brought into the evidence and which was in the nature of a personal attack.

9368. I do not call this a personal attack. Here it is

* *See "Collected Papers for the Research Laboratories of the Royal College of Physicians, London, and the Royal College of Surgeons, England." Edited by T. G. Brodie* (1903). L.L.-af-H.

said that the statement which you make in that book about this marmot is not accurate?—I bring evidence to show that Mr. Thane's criticism upon our book is incorrect.

9369. (*Mr. Ram.*) Will you forgive me for saying that I am not going into his criticism, and I certainly am not making any attack upon you. Is there any evidence which enables you either to disprove or accept Mr. Thane's statement that he examined the body of that marmot and found that the spinal cord had not been divided?—I can prove first that experiments had been performed on this marmot before.

9370. We will leave that for the moment, because I am dealing with the dead marmot?—In the second place we never laid claim to having seen the actual division of the spinal cord of this marmot. It is very difficult to answer such a complicated question if I am not allowed to give my answer fully.

9371. (*Chairman.*) It is a very simple question?—The marmot, according to Mr. Thane's criticism, was in a state which resembled that in which the spinal cord has been divided. That has been acknowledged by Mr. Thane. He said that it was in a state which resembled paraplegia. We drew that inference from seeing the marmot and from my experience of other marmots, because I have lived a great deal in the Swiss Alps, and as a humble student of natural history I have observed marmots, and I may say that if the spinal cord had not been divided that marmot was very different from other marmots. I have not, of course, made a post-mortem on this marmot.

9372. (*Mr. Ram.*) But you see Mr. Thane has?—Mr. Thane says he has.

9373. I want to get it quite concisely. You state here as a fact that you once saw a marmot the spinal cord of which had been previously divided. Mr. Thane says that he examined the body of that marmot after death and found that its spinal cord had not been divided. Do you admit that you made a false deduction from what you saw?—I do not admit that we made a false deduction from what we saw, because I have no evidence sufficiently strong to convince me that we did. I have not seen that marmot myself after its death.

9374. Will you not accept the evidence of Mr. Thane?—I should hesitate to accept the evidence of Mr. Thane because he had just made a most inaccurate statement by saying that that marmot had never been experimented on before save for having its temperature taken.

9375. Then I am to take it that this distinct statement of fact by Mr. Thane is one that you decline to accept?—I decline to accept it on the ground that he had just made an inaccurate statement.

9376. Will you admit that the state of the marmot was one which might lead you to make a wrong deduction?—I need not admit that, because the marmot looked as if it had had its spinal cord divided.

9377. And therefore you inferred that it had?—Yes.

9378. And you still stick to that inference?—I see no reason not to stick to it.

9379. Then I leave that.

9380. (*Chairman.*) Do you think that because in your opinion Dr. Thane has made a misstatement about the number of experiments on that marmot it justifies you in dismissing the whole of his evidence?—I think that when Mr. Thane says that that marmot was never experimented upon save for having its temperature taken, and it had actually been subjected to fasting experiments—starvation experiments—I am justified in not accepting the second part of his statement.

9381. But supposing we thought that you were mistaken in your view about this marmot, you would think it very unfair that we should not accept any of the statements you have made in the "Shambles of Science"?—I am sure that the Commission will carefully scrutinise anything that I have said.

9382. We certainly shall, and, I hope, fairly.

9383. (*Colonel Lockwood.*) You want to bring Dr. Pembrey in evidence?—I have got the actual paper by Dr. Pembrey,* who owned this marmot, showing that starvation experiments had been performed on this marmot in the autumn time lasting 52 hours, 50 hours, and 42 hours at a time, when the marmot is in the greatest need of feeding, being an hibernating animal.

9384. (*Mr. Ram.*) What you saw was capable of one of two explanations, either that the animal was hibernating or that its spinal cord was divided, is that so?—No, it was not capable of that first interpretation which you refer to, because if it had been hibernating it would not have bitten the demonstrator, and Mr. Thane does not deny that it bit the vivisector, which really is the chief point in our bringing in that marmot.

9385. Then you ask us on this evidence, which we have to balance, to say that this statement of Mr. Thane's is and must be to his knowledge untrue?—I do not ask the Commission to accept that. I only beg the Commission to excuse me from accepting Mr. Thane's statement.

9386. What alternative can you suggest to us that we can find?—I can only leave the question with the Commission to draw their own conclusion between the two statements.

9387. In that same chapter which begins about the marmot you give an account of an experiment on what you call "The Quiet Cat"; that is at pages 37 and onwards?—Yes.

9388. Do you suggest, or do you wish the reader to believe, from this account, that that cat was under anæsthesia the whole time of the operation or not?—May I just look at the chapter.

9389. If you please; it is only three pages?—That cat was quiet all the time, and artificial respiration was, according to our observations, maintained. As no operation had been performed which necessitated artificial respiration (because sometimes it is necessary or the animal will die) we drew the conclusion that the animal was under curare, because artificial respiration would then be necessary, and, of course, if the animal was under curare it would be absolutely quiet.

9390. Is the conclusion which you desire the reader to draw that the animal was under curare and not under an anæsthetic?—The conclusion might be drawn that the animal had had both curare and an anæsthetic, and when curare has been given an anæsthetic is highly unreliable, and the animal would lie quiet without further doses.

9391. Will you show me anything in this chapter on "The Quiet Cat," which gives any indication to the reader that there was any anæsthetic employed at all?—No, I do not think anything is said about an anæsthetic.

9392. You have just told me that the animal, in your opinion, might have had both an anæsthetic and curare administered to it?—We do not say anything about an anæsthetic for the reason that nothing was said to the students.

9393. That is what I complain of. You have just said that, in your opinion, the appearance of the animal was such that both an anæsthetic and curare might have been administered?—I said that they might have been; but, if I might continue, our inference was that no anæsthetic had been given because we did not see any administered; there was no smell of ether or chloroform, and nothing was said by the lecturer about an anæsthetic having been given.

9394. (*Colonel Lockwood.*) Who did this experiment?—Dr. Bayliss. All the experiments at University College described in "The Shambles of Science" were by Dr. Bayliss.

9395. (*Mr. Ram.*) Then I understand that you draw the conclusion yourself, and that you wished to communicate it to the reader that this cat was not under any anæsthetic at all?—We drew the conclusion that it was curarised only.

9396. (*Chairman.*) Did I catch rightly what you said just now that all the operations described in the "Shambles of Science" were by Dr. Bayliss?—All the operations referring to University College were by Dr. Bayliss. May I add to my answer in conclusion that we do not state definitely that the animal was not anæsthetised.

9397. (*Mr. Ram.*) So I gathered. I asked you whether there was anything to indicate that it was?—It was not sufficiently indicated to us to enable us to state such a thing positively.

9398. In the case of the "Dog that Escaped" which begins on page 67, was that dog, in your opinion,

* "*The Respiratory Exchange during the Deposition of Fat*," by *M. S. Pembrey, Journal of Physiology, Dec.*, 1901.

Miss L. Lind-af-Hageby.

5 June 1907.

under anæsthesia the whole time that it was under the experiment?—That dog we describe as struggling until curare was injected, and I note that Mr. Thane does not deny that curare was administered.

9399. He says that it was?—Yes, and so do we in the "Shambles of Science," and after the injection of curare the animal became absolutely quiet.

9400. Do you know that Dr. Thane also says "anæsthesia was kept up the whole time by pumping air charged with a known amount of anæsthetic through the lungs"?—Yes, that is a distinct contradiction of what we say in the "Shambles of Science."

9401. It is?—We say that no arrangements for artificial respiration had been made. And there again I must stick to what we have said for this reason, that after that particular demonstration we went up to the animal and stood near it for some five minutes after the other students had gone, talking to the laboratory boy, and I had ample opportunity of observing at that time whether artificial respiration had been maintained or not.

9402. Do I rightly understand that it was your belief then, and is now, that that animal was under curare only and had never had any anæsthetic at all?—That is my belief.

9403. Did you ever make any complaint to the Home Office about it?—We never made any complaint.

9404. There was, as you believed, a very gross violation of the law and horrible cruelty?—Yes.

9405. And you made no representation about it?—No, and our book was not written for the purpose of showing how the Home Office administers the law in England.

9406. (*Chairman.*) I do not think Mr. Ram's question referred to the book, but to what you saw. Whether you had written the book or not you made no complaint?—I see. I beg your pardon.

9407. (*Mr. Ram.*) You made no complaint at all?—No.

9408. At page 147, at the end of what you describe as "A Grand Demonstration," you say: "We meet the boy carrying the miserable white rabbit into the lecture room again"—did you at the time when you wrote that believe that the animal, the miserable white rabbit, was alive or dead?—When the animal was brought in again we had no opportunity of observing whether it was alive or dead; we simply put in the book that it lay absolutely still. It had been taken away from the room because it struggled. It might have been alive or it might have been dead. We do not insist on its being alive; the description is merely general, and gives no details to that effect.

9409. What was the inference which you intended the reader to draw from that sentence?—Either that the animal at that time was properly anæsthetised or it may have been that it was dead. I say that it was impossible for us to draw any inference; you cannot if you merely see an animal carried in when you are passing out of a door and you see it is lying absolutely still.

9410. You notice that in this case again Mr. Thane says: "An anæsthetic (ether) was used the whole time; it was given just in the same way, and under the same conditions, as in an operation on man"?—Yes; and the whole chapter "A Grand Demonstration," in our book describes how carefully ether was being given. We begin by saying "There is a strong smell of ether meeting us as we walk up the stairs."

9411. Do you think that the animals referred to in this "Grand Demonstration" suffered anything, or that they suffered nothing?—I believe that the animals, as we have endeavoured to show, continually came to, and I see that Mr. Thane does not deny that. He says, "There was probably some movement now and then as the effect of the anæsthetic began to fall off. More ether was at once given." That is exactly the same as we describe.

9412. He also says: "The so-called 'violent struggling movements' of the rabbit are greatly exaggerated. As explained by the lecturer (see p. 143), they are the reflex working of the muscles, excited by the injection of any depressor substance; they occur, as happened here, in deep anæsthesia"?—Yes, that would imply the purely reflex effect of such injection, but that is not what we referred to.

9413. Did you see anything there which enables you to say that it was not purely reflex action?—The suggestion throughout this chapter——

9414. Please answer the question?—May I say that throughout this chapter, so far as I can remember at the present moment, we do not suggest that everything was not done to anæsthetise the animals.

9415. Do you suggest that the animals suffered any pain?—We suggest that the animals kept coming to, and that everything was done to put them under the influence of the anæsthetic again.

9416. Is it your suggestion that in the course of that experiment they suffered, or that they did not suffer?—There may have been some suffering on return to consciousness.

9417. (*Chairman.*) Do you make any suggestion that in that experiment the requirements of the Act were not complied with?—No, that suggestion is not made in that chapter. The suggestion is rather made of the difficulty of anæsthetising these three animals, and the nature of a vivisectional experiment versus a surgical one.

9418. (*Mr. Ram.*) I want to read to you one expression in your book, and to ask you to what it applies. To whom do you intend this sentence on page 68 to apply: "The tormented long for their freedom, but the tormentors fight the merciful death. They are artists in the black art of producing the utmost agony, while the gateways through which death could enter are carefully watched; but sometimes they are not clever enough"; that is in "The Dog that Escaped"?—That is not meant to apply to any special vivisector; it applies to the whole system.

9419. And to everybody who practises vivisection?—The style of this book is not like a law report or anything official, like an inspector's report; we say things which have a general application, and not only things which have a special application.

9420. Then you deny that it has a particular application to anybody whom you could name?—I think it is quite clear to anybody who reads it that it refers to vivisectors generally, and to vivisected animals generally.

9421. Have you ever in England seen anybody, any operator, who, in your opinion, endeavoured to produce the utmost agony while watching the gateways through which death could mercifully enter?—I have read of many, as, for instance, the experiments of Mantegazza in Italy.

9422. May I take it that these words are not, in your opinion, applicable to anything you have ever seen in England?—They are applicable to the whole system of vivisection.

9423. In England as practised to-day?—In England, too.

9424. As practised to-day?—Of course, if you read it very literally word for word, and take it to pieces as if it were, as I say, the report of an inspector, perhaps, I cannot say that I have ever seen any vivisector who is an artist in the black art of producing the utmost agony; but from reading the whole literature of vivisection I know that there have been such.

9425. I am asking you whether here in England, under the law as it exists to-day, you can give us any instance of any person whom you have either seen in England or read of in England, who has produced the utmost agony, and carefully seen that death did not occur?—I am sure that I can give an instance of that.

9426. Will you give us one, please?—Firstly, all vivisectors generally——

9427. Please leave the vivisectors generally. I ask, Can you give us any instance in which in England since this Act came into operation those words could be justly applied?—Then I must say that the method of vivisection in itself is an attempt to stop death because death would interfere with the experiment.

9428. (*Chairman.*) Surely you can answer the question a little more directly?—Then I can say that there are vivisectors at present licensed and holding certificates in England who, I think, would be quite capable of exercising the "black art of producing the utmost agony, while the gateways through which death could enter are carefully watched."

9429. (*Mr. Ram.*) Will you give me the name of one person?—I can give you the names of several. I give you the name of Dr. E. Klein, who in 1906 held three

certificates exempting him from the obligation to use anæsthetics.

9430. Any other?—I can give the name of Dr. Schäfer, who in his last evidence before the Royal Commission exhibited the greatest callousness with regard to frogs.

9431. Any other?—I can give you the name—I hope I do not give offence to the Commission—of Sir Lauder Brunton. I quoted some experiments of his in my former evidence which I considered callous and brutal.

9432. Any other?—Am I supposed to go on?

9433. I am asking you for any that you desire to give. You assert that that is, in your opinion, the state of things to-day under our present law here in England?—If the tendency of vivisectors be to do cruel things, I do not think there is any power of stopping them in England, neither in the law as it stands nor in its administration as it is now administered; there is any amount of liberty under the administration of the law in England.

9434. You believe that these people whom you have named are all capable of doing this act—of producing the utmost agony while the gateways through which death could enter are carefully watched?—I trust I have not mentioned any name without giving a reason for so doing.

9435. Now, can you give me, please, any instance in which any one of these persons—take Dr. Schäfer, for instance—has been guilty of anything like this?—Certainly, if I am allowed to read his evidence before the last Royal Commission.

9436. What is the date of that?—It is the last Royal Commission.

9437. That would be before the present Act was passed?—Yes, the last Royal Commission on Vivisection.

9438. After which the Act was passed?—Yes.

9439. You recollect that my question was under the Act to-day; still, I do not want to exclude anything?—I did not quite catch that question before.

9440. What I asked you was: Can you give me instances either of people or of operations since the present Act was passed which justify this definition of yours?—I think I should be able to do it if you will allow me a few minutes to think.

9441. Perhaps you would like to do it after the adjournment.

9442. (*Chairman.*) Will you let me ask you, before we pass from these words in this chapter, "The Dog that Escaped," do you consider that in the case of the dark-coloured dog, which you call "The Dog that Escaped," the operator and demonstrators were "artists in the black art of producing the utmost agony while the gateways through which death could enter are carefully watched, but sometimes they are not clever enough"; and then (after three dots) you go on, "There is a dark-coloured dog somewhat resembling the Dalmatian," and you describe the experiment. Did you consider that those who were operating upon this dog were such artists as you describe there and guilty of what you describe there?—I think that in writing that passage ——

9443. Would you kindly answer the question?—Yes, I am answering it, and you must allow me to say that I feel the responsibility of what I am saying, and therefore I cannot answer very quickly; I must think before I answer. In writing that passage we had in our minds a number of vivisectors generally, and also—allow me to finish—the two operators upon that occasion.

9444. But do you consider that what happened to the dark-coloured dog described in this chapter is an illustration of that "black art of producing the utmost agony while the gateways through which death could enter are carefully watched, but sometimes they are not clever enough"?—Yes, it is an illustration, because they sought to prevent death and failed.

9445. You tell us this about the dog as an example of the present treatment of animals?—It can be taken as an example.

9446. Do you mean it as an example?—Yes.

9447. You do?—Yes.

9448. I thought you told us before that you did not think that in this case the Act was not complied with?—No, not in this case; that was in relation to "A Grand Demonstration."

9449. Then you do mean to say that this was a case in which—Dr. Bayliss, was it?—Dr. Bayliss and Professor Starling.

9450. In which they were acting the part, in treating this dog as they did, of "artists in the black art of producing the utmost agony, while the gateways through which death could enter are carefully watched, but sometimes they are not clever enough"?—Yes, it may be taken like that.

9451. (*Mr. Ram.*) There is one other quotation that I want to ask you about. On page 152, under the heading of "Vivisection Bankrupt," you say this: "In the pain-tortured bodies, trembling under the sharp steel, bathing in their own blood, and in vain trying to tear the straps that fasten them to their crosses of agony, twitching under the piercing currents of artificial electricity, there is no trace left of the normal life in the nerves, in the blood, in the wonderful co-ordinated mechanism of the internal organs." Does that relate to animals which are not under any anæsthetics?—That chapter relates to vivisection generally.

9452. Do you intend in that paragraph to allude to animals under anæsthetics or to animals not under anæsthetics?—That paragraph should be read, as I pointed out in my former evidence, in connection with the paragraph that follows. The two paragraphs were written to show that vivisection is always performed under abnormal conditions—(1) pain and (2) anæsthesia.

9453. But do you believe that these "pain-tortured bodies," of which you speak in that paragraph, were under anæsthesia or not?—We do not speak of any special experiments. This is a general chapter on vivisection in England, vivisection throughout Europe, vivisection all over the world.

9454. That is what I am trying to get at. Do you present this as a fair and true representation of vivisection as practised in England to-day, that animals have their "pain-tortured bodies, trembling under the sharp steel, bathing in their own blood, and in vain trying to tear the straps that fasten them to their crosses of agony"? Is that a true representation of vivisection as practised in England to-day?—Yes, it is a true representation according to other descriptions of vivisectional experiments given in other chapters.

9455. Will you tell me of any experiments that you have seen in which any one or all of these different ingredients of pain were present?—I can refer you to "The Dog that Escaped," which we have just been discussing.

9456. Is this passage, then, intended to represent and sum up your opinion of what you yourself saw?—Not only of what we saw; that added to our general experience through reading of what vivisection is and the experience of others.

9457. And you believe that that goes on to-day in England?—Yes, I believe that that goes on to-day in England.

9458. And you believe that what you have described in this paragraph is a truthful representation of certain experiments which you saw?—Yes; and, added to that, my further experience and knowledge of vivisection.

9459. And you made no complaint to the Inspector or to the Home Office?—No, I was not there to make complaints to the Inspector; I wished to see how vivisection is practised in England under the Act of 1876. It is supposed to be more humane here than in other countries.

9460. And you represent that as a fair description of it?—Yes.

9461. (*Dr. Gaskell.*) I want to ask you a question with respect to what you have just told Mr. Ram about "The Dog that Escaped." Am I to understand that curare only was given and no anæsthetic?—According to our impression curare only was given.

9462. And there was no artificial respiration?—There was no artificial respiration according to our observation.

9463. The object of the demonstrator was to kill that dog, I presume?—No, because a slight dose of curare does not kill a dog. Dr. Bayliss said, "The animal is now slightly curarised."

9464. Have you ever seen or heard of anyone who was going to slightly curarise a dog who would not put in

Miss L. Lind-af-Hageby.

5 June 1907.

a tube for artificial respiration first?—I have frequently read that a slight dose of curare does not stop respiration.

9465. But would he not put in a tube first, on the possibility of respiration being stopped?—I think it is quite possible that that would not be done in the case of a very slight dose. Our contention here is that Dr. Bayliss meant to give a very slight dose and gave a stronger dose than he intended, and therefore respiration failed.

9466. You did not see that tube which was in the trachea?—No, we saw that there was no tube in the trachea.

9467. Then Dr. Thane's statement there is absolutely untrue, is it? He says, "Anæsthesia was kept up the whole time by pumping air, charged with a known amount of anæsthetic, through the lungs—*i.e.*, artificial respiration was carried on. Curare was administered, and the artificial respiration, the air still charged with anæsthetic, was kept on as before"?—Yes, that is a distinct contradiction.

9468. Contradiction of what?—Of our description in the "Shambles of Science."

9469. But is it a contradiction of fact?—Yes, it is a contradiction of fact.

9470. Then you say that that is a deliberate statement on the part of Mr. Thane and whoever it was he consulted—Mr. Bayliss—to deceive this Commission?—Mr. Bayliss may not have remembered, because no notes are kept of demonstration experiments, according to the evidence given at the trial.

9471. Mr. Thane goes on further to say: "The apparatus for artificial respiration broke down. The professor went to put it right. The experiment was continued, but the apparatus gave way again. Respiration was stopped, and the animal died of asphyxia." It is a very circumstantial account—invented, I presume, according to you, by Mr. Thane and Mr. Bayliss?—I can pass no opinion as to whether it is invented. I simply say that I do not agree with it.

9472. I will leave it at that. You have quoted Professor Claude Bernard with respect to the action of morphia, and I presume that you have read various papers of his, have you not?—I have read a good deal of his work.

9473. He says, in talking of the action of morphia, "However, the sensibility persists, for if we pinch the animal it moves and cries"?—Yes.

9474. That is what you saw?—Yes?

9475. And from that you conclude that Claude Bernard considered that the animal felt pain?—Yes.

9476. But he goes on to say: "But these are only movements due to a very obscure kind of perception. In reality he does not dream of getting into a rage, or of defending himself; his intellectual faculties are completely in abeyance"?—Yes, that is no contradiction.

9477. That does not look, does it, as though he considered that the animals suffered pain?—As a supplement to that I put my quotation from Claude Bernard on the effect of morphia, where he says that the animal "feels the pain but has lost the idea of self-defence."

9478. In this case he is defining what he means by feeling pain—that is, movements are due to a very obscure kind of perception?—But he says distinctly that it "feels the pain." He cannot say anything clearer.

9479. This is a further statement of Claude Bernard in his "Lessons on Anæsthetics and on Asphyxia"?—That is the book I have brought with me to-day, and that book has a great many statements which I can show you proving that Claude Bernard did not consider morphia an anæsthetic for dogs in any sense. I have carefully read through this book before coming to-day.

9480. On page 219 he says distinctly: "Morphin sends to sleep pain which has its seat in the sensorium"?—He says, on page 219, that he injected a young dog with 5 c.c.'s of a solution of morphia hydrochlorate, and that resulted in—yes, you are right—that is an exception.

9481. An exception?—Yes, that is an exceptional case, and entirely different to that given on p. 222, and on other pages; but even then he shows that "Si l'on reveille le chien ou seulement si on le pince" physiological functions at once become more normal.

9482. I did not understand it to be an exception. Again, as illustrating the action of morphine, you will find on page 235: "After the injection of 1-2 centigrammes of hydro-chlorate of morphia into a man, the first effect of inhalation of chloroform given in the usual manner is to produce a state of analgesia, with retention of the intelligence, the sense and the power of voluntary movement"?—Yes, but I do not propose to deal at all with the effect of morphia on man. My evidence last time was rather to show that dogs are extraordinarily insusceptible to morphia, and I have here another quotation from Claude Bernard.

9483. I wanted to ask you whether you did not realise that Claude Bernard says there that the action of morphia with a very slight dose of chloroform is to remove all pain although consciousness persists and the sense and the power of voluntary movement?—Neither am I dealing at the present moment with morphia and chloroform; that makes all the difference in the world.

9484. But the chloroform is so slight, according to Claude Bernard, that consciousness still persists with retention of the intelligence, the sense and the power of voluntary movement, but that the action of morphia *plus* a slight amount of chloroform is to remove all pain?—Then my answer is, that if that be the case in man, man is far more susceptible to morphia than a dog would be.

9485. But I was simply stating that Claude Bernard's argument is that morphia removes pain?—I cannot accept that statement of what morphia does with regard to man as being equivalent to what it does with regard to a dog.

9486. Do you not believe—it is not a question of belief; do you not know that in these cases of anæsthetics being given, the sensation of pain is one of the first things to go?—That is not always the case. The sensation of pain may persist. I have quoted Professor Flint to show his opinion upon that point, and I believe that is very often the experience of people who have been under anæsthetics.

9487. Is it not a very common experience to find that pain does go even although apparently consciousness still exists?—It is a common experience; but, on the other hand, it is a common experience that pain does not go.

9488. Have you ever had laughing gas?—I have; I was just describing that when you came in this morning. I had laughing gas once for the purpose of extracting a number of pieces of a tooth which were left in my jaw, and although I was unconscious to a certain extent, I felt the pain of the operation all the time; though when I came to perfectly I very soon forgot all about it.

9489. And then when you were asked the question whether you felt any pain you said "No"?—I did not. I said that I had felt the pain.

9490. Is it not often the case that patients under a slight anæsthetic like laughing gas, not only cry out but make violent movements when the tooth is drawn, and afterwards assert that they felt no pain at all during the operation?—That is often the case; but it is equally often the case that people do feel pain and yet are in a kind of subdued state; as, for instance, when slight doses of chloroform are given to women in cases of labour. I know of one instance of a woman who felt pain all the time. She lay in a state of subdued hushed consciousness, but was afterwards able to state definitely that she felt all the pain, though she was unable to give any expression to it. That is a personal acquaintance of mine. There are such cases.

9491. That meant that a very little more chloroform might have been given with advantage, did it not?—She could not ask for more, because the people round her thought that she was unconscious and talked of her as being unconscious, and she heard them talking of her as being unconscious.

9492. (*Dr. Wilson.*) She was in a cataleptic condition?—She was in a cataleptic state.

9493. (*Dr. Gaskell.*) Do you not notice that Claude Bernard speaks of the persistence of sensibility in the case of morphia; it is the persistence of sensibility that he speaks of, and then later on he defines what he means by sensibility?—Yes.

9494. And he goes on to point out the difference in the use of the term sensibility by philosophers and physiologists?—Yes.

9495. He says that "according to the former sensi-

bility is the sum total of the psychical reactions provoked by external stimuli. For the latter, for us, it is the sum total of the physiological reactions of every kind provoked by external stimuli"?—Yes.

9496. Do you not understand by that that he does not consider that the retention of sensibility after morphia means necessarily the retention of consciousness?—I think, from reading Claude Bernard's work on this subject carefully, one comes to the conclusion that he does mean by his *sensibilité* what we mean by sensitiveness. I remember I was once attacked in a book by a Swedish vivisector on this very subject, and in my answer I pointed out the various meanings attached in French to the expressions *sensibilité, irritabilité sensitive*, or *excitabilité sensitive;* and there is no doubt that by the first Claude Bernard means the persistence of conscious sensation. For instance, here on page 222 he says: "Though in a state of torpor the animal is excitable and sensitive. But if the nerves have not lost their *sensibilité* they are at least dulled." And he adds that the animal is sensitive to pain if it be pinched or subjected to stimulation. Besides, there is the distinct phrase "signs of pain"—*les signes de la douleur*. What could be clearer?

9497. But in this other case he says "*sensibilité.*" "However the sensibility persists, for if we pinch the animal it moves and cries." And later he states that "for the physiologist in addition to the conscious sensibility there exists also an unconscious sensibility"?—But if he has mentioned *les signes de la douleur*, there can be no doubt about it.

9498. Afterwards he distinctly asserts that morphia sends to sleep pain," as I showed you?—I do not think it has that meaning, for he has previously said (p. 211): "L'action de la morphine diffère tout à fait de l'anesthésie."

9499. Now, I would like to go from Claude Bernard to your own evidence?—My printed evidence, or the book?

9500. The evidence in the book. Will you turn to your chapter headed "An experiment that 'is not supposed to be useful'"?—Yes.

9501. You tell us, "The animal is now deeply under morphia"—and then throughout the whole of the experiment you further speak of it as "absolutely still." Then you say, "We can be almost certain that the dog has been also curarised, because it is absolutely still with the stillness that is characteristic of the 'hellish oorali'"?—Yes.

9502. And therefore all we know from this statement of yours is that the dog was under morphia, and in your opinion had curare as well?—Yes.

9503. But you will see from Dr. Thane's evidence that there was no curare?—Yes, I have seen that he says so.

9504. Then does not your evidence show that morphia alone kept that animal still?—Yes. All the evidence that I have given on morphia has gone to show that morphia is a drug which has the power of making an animal lie very still—not a cat, but a dog—and that the animal may be sensitive all the time, and that it would respond to painful stimuli.

9505. But these were painful stimuli and it lay still—it did not respond?—Yes.

9506. Therefore, according to your own evidence, morphia was very distinctly an anæsthetic in that case?—According to my evidence, if we were certain that the dog had not also been curarised it would show that it had lost its power of self defence.

9507. But you find now that that is not so?—I hear that Mr. Thane mentions that it is not so; I do not find that it is not so.

9508. Then, may I ask, do you still stick to it that the animal was also curarised?—I stick to all the things that we have written.

9509. It was under curare?—Certainly.

9510. And this is not evidence of the anæsthetic properties of morphia?—No.

9511. This dog had curare?—Yes, because it had every sign of having curare.

9512. Although we are told definitely and absolutely that no curare was given?—Yes.

9513. Take another case, "Scarcely any Anæsthetic"?—May I add that our reason, and a very strong reason, for concluding this, is Dr. Brodie's own statement in his book, where he distinctly states that he prefers curare because it is essential to the only satisfactory method.

Miss L. Lindaf-Hageby.

5 June 1907.

9514. Which are you referring to now?—"The only completely satisfactory method."

4514A. I was speaking of "Scarcely any anæsthetic"?—But the physiologist was Dr. Brodie on both occasions, and he has written in his book for students very clearly on his preference for curare.

9515. "Not supposed to be useful" was the one. Was that Dr. Brodie?—Yes.

9516. In this case "Scarcely any Anæsthetic," at page 49 in the old edition, you say: "'The animal is so profoundly under morphia we have scarcely had to give it any anæsthetic at all,' says the lecturer"?—Yes, those were the words of Dr. Brodie.

9517. I understand that to imply that the main narcotic given there was morphia?—Yes, according to Dr. Brodie's own words; he has not denied it.

9518. No, I do not want to deny it?—I believe he has not denied it through Mr. Thane.

9519. I only want to point out to you that you say on the previous page: "The strings which hold the dog's legs are loosened. The assistant demonstrator lifts up first the hind legs and then the body several times, whilst the lecturer holds down the animal's head." Would not the dog have made any movement, if it had not been anæsthetised, under those circumstances? The limbs are free, the dog is capable of moving them as much as it likes; it is pulled up and down in this way; if morphia was not an anæsthetic would not the dog have moved?—I have never denied that morphia has the power of keeping a dog quiet. Morphia can keep a dog quiet.

9520. What, when it is in pain?—If it were in a state of narcosis, it is quite possible that it would be quiet for that moment when the legs were loosened from the board.

9521. But it was in pain all the time, according to you. Do you mean to say that it would not demonstrate its pain if it was conscious and was capable of doing so, by the legs being moved?—How could it demonstrate its pain by moving the legs when the assistant demonstrator held both hind legs? How could it struggle with its hind legs when he held them both for the moment, if it had wanted to do so? If I take up a dog which is fastened to an operating table and lift up its hind legs and hold them together with my hands, that dog cannot struggle.

9522. Let us take "Long Experiments." This again is a case of morphia and a little chloroform?—Yes, according to Professor Halliburton.

9523. And you say throughout that the animal was quiet. It is not an instance that you give of any evidence of pain?—No, we do not give that as an instance of evidence of pain; we could but see that the animal was quiet, and we honestly put it down and recorded it.

9524. And yet what was mainly given was morphia?—I do not say that the animal did not suffer pain. I do not know. I could only record that it was quiet.

9525. Then I understand that in these three cases of morphia which I have quoted to you, although the animal was in pain, it remained remarkably quiet as though it was properly anæsthetised, and did not show any sign of that pain by struggling and so on?—I do not know whether that is so in the three cases you have quoted.

9526. I understand from your own statement that in these three cases the animals were very quiet?—Then it must be so. I cannot at this moment recollect which three they were. If that be so, it is just because morphia does make a dog quiet. In two of the experiments I believe chloroform was given as well.

9527. I have a question to ask you on "The Only Completely Satisfactory Method." Here again your remark (on page 134) is: "The director of the laboratories is anxious to make the most of the dog that is so nice and quiet to experiment upon"?—Yes, the director was Dr. Waller. He is the director of the laboratory.

9528. Do you mean to say that that quietness was not due to properly given anæsthetics?—We inferred that it was due to curare, because Dr. Brodie was the lecturer, and he has expressed his preference for curare. He said nothing about having given an anæsthetic, and there was no smell.

Miss L. Lind-af-Hageby

5 June 1907.

9529. Here again I suppose you would not agree with Dr. Thane's statement: "The assertion that curare has been used is false. The animal was anæsthetised with chloroform throughout, under the superintendence of the director of the laboratory"?—The director of the laboratory did not superintend any giving of chloroform in our presence during the hour and a half, and if you give chloroform you have to give every five minutes, or more frequently. I do not think Dr. Waller would say that he did do that, because that I should think would be impossible.

9530. Dr. Thane goes on to say: "'Artificial respiration is being kept up'; quite true; but the writer omits to state that the air pumped in was passed through a bottle containing, and so became charged with, the anæsthetic"?—That is his statement.

9531. Is not that a possible method of giving chloroform?—Yes, and we stated that artificial respiration was kept up.

9532. That you omitted to see, apparently?—But no chloroform was given in our opinion.

9533. Because you could not smell it?—We could not see any bottle.

9534. No, because the bottle was in another room?—Nor could we smell it.

9535. It is the same as in the case on which the action was. There, again, because you did not see the chloroform you stated again and again that there was no anæsthetic given. In each of those cases anæsthetics are given in the same way, with chloroform, the air rising through it?—But on other occasions, in the University of London, anæsthetics were given in the usual way through dropping the anæsthetic on to a cloth, and then everybody could smell it. On this occasion there was no such indication.

9536. And you made a mistake?—I do not acknowledge that I made a mistake. I saw the pump; we describe how we saw the pump and heard the hissing sound, but no bottle.

9537. If you do not acknowledge that you made a mistake, I say no more?—Certainly, I do not.

9538. There is one more question that I should like to put to you on this book. You speak in one sentence, I think it is in that same "A Grand Demonstration," on page 144, of the rabbit moving its paws: "When the table with the operation board is now lifted up, and the rabbit carried to the place in the middle where the dog had been, the little animal again stretches up its fore-paws with claws thrust out"?—Yes.

9539. Are you aware that in physiological laboratories that movement of extension of the paws is a sign of asphyxia?—There was no asphyxia then. The animal was, according to Mr. Thane, asphyxiated later on in another room.

9540. Will not asphyxia take place if chloroform is pushed too much?—It was not pushed too much, because no chloroform was given. It was ether.

9541. Ether is still more restricted?—According to Dr. Thane, and, I think, it is admitted, the animal had to be taken out to be killed because it came out of the anæsthesia. There was no question of asphyxia at all, neither according to our account nor Dr. Thane's.

9542. Do not you know that when a rabbit is under an anæsthetic, either chloroform or ether or A.C.E. mixture, as soon as the experimenter sees that movement of the paws he gives less chloroform, because he knows that he is overdoing it?—That is quite possible; but that was not the case here.

9543. It is the beginning of asphyxia in consequence of an overdose of chloroform?—It would entirely contradict Mr. Thane if what you say is true; because he acknowledges, I believe, in his pamphlet that the rabbit was taken out to be given more anæsthetic.

9544. But that is afterwards?—He does not say that there were not violent struggles and movements of the rabbit. He says that they were "greatly exaggerated" by us.

9545. I was only referring to that movement of the paws. I wanted to know whether you recognised that movement of the paws does not necessarily mean returning consciousness?—Yes; but I also contend that upon this occasion it could not mean asphyxia or any danger from too much anæsthetic, because, according to Mr. Thane, the animal was sent out to be killed by an overdose of ether. If it had already had an overdose of ether, it would not have been sent out to be killed.

9546. (*Dr. Gaskell.*) You spoke of physiologists using light and deep anæsthesia?—Yes.

9547. Are you acquainted with Hooper's experiments on the recurrent laryngeal?—I am not.

9548. Do you not know that with ordinary anæsthesia, when that nerve is stimulated you get closing of the glottis, and that when anæsthesia is pushed deeply you get opening of the glottis. You have not heard of that?—I am not acquainted with those special experiments. I do not know to which you refer.

9549. I only wanted to know whether you were aware that the peripheral nerve alters its effect according to the condition of anæsthesia. That the recurrent laryngeal opens the glottis when the anæsthesia is deep?—Of that, I think, I am generally aware—not of those special experiments—because that is one of the reasons why I have stated that physiologists prefer light anæsthesia, as deep anæsthesia sometimes interferes.

9550. This is the peripheral nerve?—Yes.

9551. That has nothing to do with the central nervous system?—Do you mean when the nerve is cut off?

9552. I mean the nerve cut off and the muscles stimulated by excitation of the peripheral end?—Yes.

9553. You do not also know of Bowditch's experiments upon the action of anæsthesia upon the sciatic of the frog?—No; of course I am not a vivisector, and even a vivisector cannot be acquainted with all experiments.

9554. I thought you had studied a certain amount of physiology?—I have studied a certain amount, but not in the way that a vivisector would.

9555. There again the evidence is that stimulation of the nerve will cause extension when the anæsthesia is slight, and the opposite effect when the anæsthesia is deeper. And do you know the difference between pressor and depressor effects upon the stimulation of an afferent nerve, according to whether the anæsthesia is deep or not?—Yes, I have some knowledge of that.

9556. And also the difference in the effect upon the respiratory centres?—Yes.

9557. How inspiration takes place in one case and expiration in the other; you know that?—I have some knowledge of that, too.

9558. Do you not see then that the reason why physiologists make a distinction between light and deep anæsthesia is on account of the reversal of effects which take place in nervous actions?—Certainly, I have seen that all the time, though, of course, not only from the vivisector's point of view.

9559. It has nothing to do with the question of pain?—It has to do with the question of pain. Thus, for instance, Professor Starling in one place refers in his book "Elements of Human Physiology," to incomplete anæsthesia, and speaks of "Pain, as evinced by the movements of an animal not fully under the influence of an anæsthetic." That would prove, in my opinion, that incomplete anæsthesia has to do with pain.

9560. But I was using your own terms, light anæsthesia and deep anæsthesia—not incomplete anæsthesia?—That is the same thing, light or incomplete, so far as I understand.

9561. That is exactly what I want to get you to see. It is not the same thing?—I have never heard that before.

9562. Do not you know that the reason why a distinction is drawn between deep anæsthesia and light anæsthesia is to emphasise the deep anæsthesia because of its reversal of the effect?—I quite see that.

9563. That is all I want to bring out with reference to that. Now, might I ask you with regard to your theory that the spinal cord of the frog is capable of feeling pain. I think I am right in saying that you rather hold that view?—Yes.

9564. I suppose I shall not be wrong in understanding that you hold that view on account of the apparently purposive activities which take place on stimulation of a nerve when the spinal cord is isolated?—In holding that view I am in very distinguished company.

9565. I only wanted to know whether that is your reason for holding it?—I have many reasons, but I cannot answer you with a single sentence. I could give a considerable amount of evidence on that point if I were allowed

9566. I thought you said that it was merely because of the purposive activities?—That is one of the reasons. I have more; I have a great deal of knowledge of these experiments.

9567. I was only asking you that because I wanted to know whether you would also hold the same view with regard to the spinal cord of a dog?—I do.

9568. That there purposive reactions take place showing that there is pain?—Yes, and I based my statement last time——

9569. Do you also hold the same view with regard to a monkey?—Certainly.

9570. And do you hold the same with respect to man?—No.

9571. You draw a distinction between a monkey and man?—Yes, I do. I could not offer an opinion about the anthropoid ape, but I do think that a monkey is sufficiently low for the spinal cord to be exceedingly highly developed in comparison with the cerebral hemispheres.

9572. Then according to you man's spinal cord is not capable of feeling pain, but you think that a monkey's is; there is that difference in the purposive activities of the spinal cord of a man and of a monkey?—Yes, I think there is a difference. I cannot be absolutely dogmatic on that point.

9573. If consciousness of pain is established because of the purposive activities upon stimulation, may I ask why you confine yourself to the spinal cord; is there not another system in the body, the sympathetic system?—Yes, but I do not think that the sympathetic system plays the same part as the spinal cord.

9574. Is there not any evidence of purposive reflexes from the sympathetic system?—Yes, there is. I do not think that any physiologist has ever put forward that the sympathetic system would be capable of any kind of consciousness; but a great number of physiologists have put forward that the spinal cord would be capable of a kind of hushed consciousness. Thus Huxley himself in 1870 read a paper entitled "Has the frog a soul, and, if so, of what nature is that soul," based entirely on these strange phenomena exhibited by the spinal cord of the frog.

9575. Are you not aware that the sympathetic system used to be looked upon as entirely independent of the central nervous system, and that they went so far as to speak of the coeliac ganglion as the brain and the soul of that system. You did not know that?—I think there has been a great deal of theorizing with regard to the solar plexus generally, and is still; I am quite aware of that.

9576. I thought you said that no physiologist had ever put forward the view that the sympathetic system was independent or capable of reacting like the central nervous system. That was the view that was always held?—I am not aware of any physiologist who would be acknowledged as a physiologist at the present day, who has put forward that theory.

9577. One great physiologist I know of was a man named Bichat?—Yes?

9578. Did he not put forward that view?—Not that I am aware of.

9579. Do you know the experiments that have lately been made on Auerbach's plexus in the intestines?—I am acquainted with them.

9580. There is evidence in those experiments that the ordinary peristaltic action of the intestine is due to nervous stimulation, owing to Aeurbach's plexus?—Yes.

9581. Would you not call that of the same character as the purposive activities that you can get from the spinal cord of a frog?—No, I would not, because they would be of an entirely different nature. The purposive activities which you get from the spinal cord of a frog, and of animals higher in the scale, present certain, what I might call mental or psychic phenomena, which I am sure would not be presented by any plexus of any kind.

9582. The one is the ordinary movement of the intestines and the other is the ordinary movement in the striated muscle; I do not see quite where the distinction lies?—The distinction lies in this, that the theories I hold with regard to the spinal cord, spinal automatism, and its power of independent action, are based not on mere movement, but on the deliberate choice in action, and on signs of consciousness which have been again and again manifested by such animals. I need only refer to Steiner's well-known experiments on frogs *contra* Goltz and to Pflüger's experiments.

9583. But upon this question of peristalsis in the intestine, there are two effects occurring: one is the contraction of one part of the intestine, and the other is inhibition of another part?—Yes.

9584. That is as purposive as the purposive movements of the muscles. It is not a simple contraction of the muscles but a purposive movement?—You are now using the word purposive in the wider sense in which it can be applied to every function of the body; there is nothing in the body which does not have a purpose; but I am using the word purposive in the sense of conscious purpose in a living creature. It is quite a different thing.

9585. I do not understand where the word conscious comes in.

9586. (*Mr. Tomkinson.*) May I take it that your general position towards the question is this: that while you are strenuously opposed to every kind of cruelty, and would do your best to minimise it, the special branch that you have taken upon yourself is the branch of this anti-vivisection?—That is so, because I consider it the worst, perhaps, of cruelties, though there are others that can be compared with it.

9587. And in regard to its practice you are, in the first place, sceptical about the possibility of total anæsthesia?—Entirely sceptical.

9588. And even if you were not so, you would think it inevitable that, either from carelessness, or omission, or indifference, at times great cruelty would be inflicted by operations?—Yes, I think so.

9589. Those are your general grounds of opposition to the system altogether?—Yes.

9590. You are not altogether opposed, if you could not obtain a complete prohibition of it, to taking instalments?—No, I am not opposed to it, but I should continue to demand abolition.

9591. In the direction of its limitation to certain animals?—No. If I had no choice I should, of course, gratefully accept the limitation of the practice.

9592. And you would also support further restrictions in regard to the prohibition of morphia and curare as anæsthetics?—I should, as preliminary measures.

9593. Did I rightly understand that you have witnessed yourself personally many operations?—Yes, I have witnessed a certain number of operations on living animals.

9594. And did you say that in two cases only you thought that complete anæsthesia was established and maintained throughout the operations; there is some confusion about the "Two cases only"?—Yes.

9595. (*Chairman.*) Does that mean two of those in the book or two of the 50 you spoke of?—All the experiments that we saw are not described, but the severer ones are described in this book.

9596. But I only meant that Mr. Tomkinson's question seemed to assume that you were speaking of only two out of the 50 operations which you had seen properly anæsthetised?—It would be an exaggeration to say two out of the 50, because during many of those 50 there was nothing which might be called real vivisection. But among those described in this book there are only two. That is the answer.

9597. I understood that was what you did say. I only wanted to make it clear.

9598. (*Mr. Tomkinson.*) You have no suggestions to make as to increase of inspection?—No, I do not believe in increase of inspection.

9599. You think that inspection is a mere formality?—As inspection is practised now it has been of no avail at all, I think, either in checking the increase of vivisection or in enforcing compliance with the Act.

9600. On the ground of its infrequency?—Both on the ground of its infrequency and other matters associated with it. I do not think the Inspectors (but perhaps that is outside the inquiry) are men we have confidence in as Inspectors.

9601. Did you notice what Professor Starling said with regard to experiments in the way of starvation, of depriving animals of food?—Yes.

9602. Did you notice that he said that he thought the mere fact of going without food was not a painful experience?—Yes, I noticed that with some surprise.

Miss L. Lind a-Hageby.

5 June 1907.

9603. And instanced the Italian faster Succi?—Yes.

9604. Who was supposed to have fasted for 40 days?—Yes.

9605. But who was afterwards found to have received something?—Was he? I did not know that.

9606. In the way of a phial, I think he did. What have you to say with regard to that? It is rather a novel idea that starvation could take place without cruelty and pain?—I should certainly consider starvation generally, forced starvation, painful. Of course a professional faster might by power of will reduce that pain to a minimum; but I saw the Italian faster Sacco come out of his fast at Hengler's Circus at the very moment he broke it, and I think he was in a very weak and bad state.

9607. Undoubtedly he was?—But I do not think that case can be at all applied to the artificial starvation of an animal that is craving for food and has no will power to put against the pain. Professor Starling gives several examples in his book of animals starved for experiments, and especially one case where an animal is starved and then made to do hard work afterwards, drawing a milk cart, which certainly would be cruel. I do not know whether he would declare that to be a painless procedure. It is at page 491 of his book. He says: "Much more efficacious than starvation in causing disappearance of the hepatic glycogen is muscular work. If a dog be starved for a day and be then made to drag a heavy milk cart about all the next day" (that is rather hard lines, I think), "there will be found only the merest traces of glycogen in its liver." A dog is to be starved one day, and then made to drag about a heavy milk cart all the next day.

9608. You described how you witnessed some operations which you thought extremely cruel on account of the imperfect anæsthesia, and you were asked whether it had occurred to you to make any representation, and you said it had not. You did not think of laying an information?—We were not there for that purpose.

9609. Were you there under any obligation of loyalty or secrecy not to do that?—No, we were there entirely as independent students for the purpose of seeing what actually took place, and we were there for the purpose of seeing how experiments are performed under the present Act. It was not for us to remonstrate with the vivisector or to make any kind of official declaration, because the result would probably have been that we should have been turned out, and the experiments would have gone on just the same. We were there to see how they were carried out without any interference from us, and it cost us very much not to interfere many times.

9610. Do you think it would be a good thing if there was a freer right of entry, by people of accredited position, to go in and pay surprise visits at times and witness operations?—I should think so, provided that those people were chosen from among those who have humane views and not among those who are in favour of vivisection, or who only advocate its scientific utility and care nothing for its moral value.

9611. I am speaking of ordinary laymen without marked opinions upon either side?—Yes, I should think that would be useful.

9612. You are aware, of course, that in foreign countries the whole practice is infinitely less humane than in this country?—I am aware of that.

9613. That is to say, there are unspeakable cruelties and horrors in France and the United States and different places?—Yes.

9614. Therefore I suppose you admit the possibility, if the practice was totally prohibited here, of driving it more abroad where they are more inhuman, and probably the sum of animal suffering might not be diminished?—That is a very difficult question to answer. You mean that English physiologists would emigrate wholesale to foreign countries?

9615. No, I do not say that; I only meant that there might be more experimentation abroad by people there already?—I do not think that. The only danger would be of a wholesale emigration of all English vivisectors to foreign countries; otherwise I think it would diminish the total sum of animal suffering.

9616. But the example of this country?—Yes.

9617. You would like this country to set an example?—Yes, I think the example would do a great deal of good.

9618. I think you said you were a vegetarian?—Yes, I am.

9619. You no doubt then appreciate very deeply a good deal of the cruelty in our slaughter-houses?—Yes, and I am very anxious that such avoidable cruelty should be prohibited by law.

9620. And also in many other ways; for instance, the trapping of wild animals?—Yes.

9621. Some people hold it to be an absolute necessity to prevent a plague of rabbits; thousands of rabbits are trapped in a very cruel manner?—I think it might be possible to destroy rabbits in a humane way, at any rate in a much more humane way than is done at present.

9622. (*Dr. Wilson.*) I think you said at a previous sitting that you had not witnessed any experiments at all on the Continent before you came to this country—in Sweden?—No, I had not witnessed any experiments in Sweden. I said I had seen the results of many kinds of experiments at the Pasteur Institute, but that I had not witnessed any actual experiments.

9623. But you held strong views on this question before you came to this country?—Yes, we did.

9624. Was that from your reading as to how experiments were carried on in Sweden and other Continental countries?—Partly from seeing the Pasteur Institute and partly from reading.

9625. And you had preconceived views as to how vivisection was carried out in this country, I take it?—I do not think we had very preconceived views as to how it was carried out in this country in particular; in fact, we expected it to be much more humane than it was, because of the Act of 1876—because of England being one of the few countries where there is any restriction. There is some restriction in Denmark and some in Norway.

9626. And when you entered at the London School of Medicine for Women, were there any experiments carried on in the physiological class there?—No, I believe not. The place is not registered for experimentation.

9627. They are not allowed there?—No. I believe Professor Cushny made a mistake in his evidence, no doubt unintentionally, in saying that the place was registered.

9628. Then did you join the advanced course of lectures on physiology at your own request, or were you invited to attend?—No, we joined them at our own wish. We sought permission in the usual way. Any medical student, any student at the London School of Medicine for Women, has the right to apply for permission to attend these courses, and we did that in the usual way.

9629. You had no intention then of writing about what you had witnessed?—No, we had no intention at the time of writing.

9630. Now, just a few questions with regard to this book, the "Shambles of Science." I take it, from all you have said, that you honestly and truthfully maintain that what you state in your book represents your impressions of what you saw, and of what you listened to?—Yes.

9631. And even as regards that experiment in that chapter, which was eliminated from the first edition, you still adhere to your views there?—I still adhere to our views there.

9632. Perhaps this is not a question which I should put, but with regard to what I may call the somewhat cynical headings of the various chapters, and somewhat scornful and sarcastic remarks that are made throughout the text, you used those, I take it, to emphasise in the strongest fashion your honest convictions as to what you saw and listened to?—The book was written under a great deal of indignation, and the scorn and sarcasm probably came out of that.

9633. But when you used the title "Fun," you had quite another feeling, which you wished to express. You did not mean that to apply to the students, did you?—Yes, in a certain way. The title was suggested by the, in our opinion, unnecessary hilarity and joking which went on whilst the dog was being experimented on.

9634. Some questions have been asked about the "Struggling Cat"; you said there was no tube in the trachea?—Yes.

9635. Dr. Thane, I think, maintains that there was

artificial respiration carried out?—No, Dr. Thane acknowledges that there was no tube in the trachea on that occasion.

9636. But does he state that there was artificial respiration?—No, he states that it is as we say, that there was natural respiration in the case of the struggling cat.

9637. And, of course, there was no tube inserted into the mouth?—No.

9638. So that anæsthesia could only have been administered in the ordinary way, by a mask?—Or by dropping it on a cloth.

9639. And you did not see anything of that?—Nothing of the kind.

9640. And the cat was muzzled?—The cat was muzzled in the usual way, and tied down on its back.

9641. And it struggled?—And it struggled, and the movements are not denied.

9642. I think all these points were brought out, but I wished to make this clear about the respiration?—In that case it struck us that as there was no artificial respiration, the ordinary apparatus for anæsthetising ought to have been at work. It is not suggested that there was artificial respiration, with a pump blowing in the anæsthetic, and therefore I may well ask who is supposed to have administered the anæsthetic on that occasion.

9643. You did not see anyone?—No.

9644. You did not see any anæsthetic administered during the whole period of the demonstration?—No.

9645. (*Dr. Gaskell.*) May I ask, did you notice a bottle on the table?—No, we did not. And may I add that even if we had noticed a bottle upon the table, the bottle could not administer the anæsthetic; you would have to have somebody to deal with the bottle.

9646. Then you deny the entire statement that "The anæsthetic was being given from a Woulff's bottle, with natural respiration. The lecturer left the theatre to get his notes, and the cat began to move; a student fetched him. He came at once, and gave more anæsthetic; this required only the turning of a tap"?—We cannot deny that the anæsthetic may have been given through a Woulff's bottle before we were there, but we deny that it was being done in our presence.

9647. You deny the turning of a tap?—Yes.

9648. "Possibly the reporter mistook the turning of the tap for tightening the strings"; that again is not true?—No.

9649. You assert that Mr. Thane and Mr. Bayliss have made misstatements there?—Yes.

9650. Then that is another untrue statement.

9651. (*Dr. Wilson.*) Now with regard to the marmot, your impression was that the spinal cord had been divided?—Yes.

9652. But, of course, we are all liable to make mistakes. Can you not imagine that that marmot was suffering at the time from paraplegia, from some cause or other; animals often do, as you know; is not that possible?—I think, as Mr. Thane acknowledges, that the animal was paralysed in its hinder parts and looked like one that had had its spinal cord divided; I cannot go further than to say that that was our impression. I have said that before, and that we have not seen it after death, and had no opportunity of verifying whether it was so or not. I can only say that if it had not had its spinal cord divided, and if I had been allowed to read my statement, which I was not, I should have been able to put in some evidence to show why it was such an abnormal marmot compared with other marmots; because it must either have been in a state of hibernation, and then it could not have bitten the vivisector; or it was in the awakening stage, when it is well known that a marmot begins to shiver, and the temperature rises exceedingly rapidly, as much as 12 degrees or more in one hour, and that when that shivering has once begun nothing can stop the marmot from becoming absolutely awake, and then from running about. This marmot lay still, and was carried about, shown to the class in this peculiar state of what looked to us as paralysis, and was neither in a state of hibernation nor in a state of awakening, nor in a state of being really awake. According to the usual knowledge that one has of marmots, neither of those three states was represented.

9653. But do you not think it is quite possible that as this marmot was retained to demonstrate this extraordinary rise of temperature under certain conditions, there would not have been any object in dividing the spinal cord?—The spinal cord of marmots is very often divided. There is a great work written on the marmot alone by a well-known French physiologist, Professor Dubois, of Lyons, which is the best known monograph on the marmot, and a considerable number of his experiments are concerned with dividing the spinal cord of the marmot in various places. Under the circumstances, therefore, seeing the state of the marmot and having this knowledge of experiments on marmots, it was the most natural and in fact the only conclusion we could draw.

Miss L. Lindaf-Hageby.
5 June 1907

9654. I will not say the only conclusion, but I admit that it might have been the natural conclusion under the circumstances. But you see Dr. Thane has made a post-mortem of the marmot, and do you not think that, after his positive statement that he found no evidence whatever of the division of the spinal cord, you must really admit that your impression must have been wrong?—I gave as my reason for not admitting that, that Professor Thane made a seriously inaccurate statement almost in the same breath as he corrects us, and I cannot feel justified in accepting his statement two lines lower down when he has just made himself guilty of such a great inaccuracy as he has done.

9655. Can you not admit this much, then—that Professor Thane may have been wrong in his inference after making the post-mortem; but surely you cannot say that he did not honestly believe, when he made that post-mortem examination of the marmot, that the cord had not been divided?—But I do not think I have said that.

9656. Yes?—I do not think I have.

9657. That was my inference—that you doubted his truthfulness, not the accuracy of his statement?—I do not think I have said that he did not honestly believe that the spinal cord had not been divided when he made the post-mortem. But I simply begged to be excused from accepting this one statement as accurate when he has just made an inaccurate one.

9658. I wanted to make that a little more clear if possible. Now about anæsthesia, you contend absolutely that as a rule light anæsthesia must be more or less incomplete anæsthesia?—I do.

9659. And in anæsthetising animals so as to ensure complete anæsthesia you would insist upon the same agents being used and the same care being taken as in anæsthetising human beings for operations?—Certainly, if the anæsthesia is to be complete or reliable.

9660. And from all you have read and seen of experiments, you believe that morphia and urethane and these other narcotics are unreliable as so-called anæsthetics?—I do, and I believe I am supported in that by veterinary surgeons of much experience.

9661. And as to the struggle of animals under operations, you have seen operations, as you have stated, on human beings under anæsthetics. Whenever a patient begins to struggle under an anæsthetic, does or does not the surgeon take that as an index or indication that the patient is coming out of the anæsthetic?—He does, and measures are taken at once to ensure deep anæsthesia by adding to the anæsthetic given.

9662. So that any movements of the limbs on the operating table, whether they may be more or less purposive or not, or reflex, are indications that the anæsthesia is incomplete, and they at once take steps to give more?—Certainly; that is always so.

9663. You have seen animals operated on?—I have seen animals operated on by veterinary surgeons, and that has been the case.

9664. With animals the same care is taken?—Yes; I was referring to an operation by Professor Hobday under those conditions.

9665. A question was asked you about permission being granted to outsiders, as it were, to witness some of these experiments. Do you think that if medical men belonging to one or other of the Anti-Vivisection Societies were allowed to be present, that would be a satisfaction to the Societies? Supposing these men were accredited by the Secretary of State, after being nominated by their Societies, to be present at any operations on animals, do you think that would give more satisfaction to the Societies?—I certainly think

Miss L Lindaf-Hageby.

5 June 1907.

that would give a good deal of satisfaction and more guarantee that those Societies have at present.

9666. If they were medical men then there could be no objection to their being present?—No, I do not think that physiologists would have any objection; at any rate they would object less than to lay people.

9667. An ordinary layman, of course, could not judge so fairly as one who had some knowledge of medicine?—No. May I add that an Association of Medical Anti-Vivisectors is being formed called the International Medical Anti-Vivisection Association; there are already some 200 members.

9668. They are not all anti-vivisectionists, are they?—Yes, they are all anti-vivisectionists.

9669. (*Colonel Lockwood.*) In London, is this?—In England and in France. There are about 100 members in England and 100 in France; it is only at its beginning.

9670. (*Dr. Gaskell.*) With respect to that statement of Dr. Thane's, which you characterise as inaccurate, on the question of the marmot, if Dr. Thane intended to imply that no cutting experiment had been made upon the marmot before, would that have been inaccurate?—He did not say that.

9671. If he had intended to imply that, would it have been inaccurate?—It would not have been inaccurate, but he said that no experiment had been made save the taking of the temperature.

9672. My question was as to a cutting experiment, cutting the spinal cord?—Yes, but he did not say that.

9673. But that might have been in his mind?—Then he did not express himself correctly.

9674. But his statement in that case would not have been inaccurate?—No, then it would not have been inaccurate.

9675. (*Sir William Church.*) I gathered from an answer that you gave to Sir Mackenzie Chalmers that you do not think that antitoxin is of value in the treatment of diphtheria?—Yes.

9676. And then you gave him a considerable number of names of, as you said, persons who had written or spoken against its use as being dangerous?—Yes.

9677. Would you kindly give the Commission the name of any person of repute, who is held in good repute by his professional brethren and the public at large, either in this country, or in Germany, or in France, or in any other country, who, having had large experience of diphtheria, both before and after the introduction of the antitoxin, is not convinced of its usefulness?—I should be most obliged if I could be allowed to send that as a note. I will prepare a list of names of people. It is rather too wide a question to answer in a minute, because there are a great many. I have the names of a great many opponents of vivisection in general, who are also opposed to serum therapy.

9678. They must be people of repute, both in their own profession and in the eyes of the public?—If you mean by that, repute among pro-vivisectionists and vivisectors, I do not think I can supply it, but if you mean men of repute among humanity at large I am sure I can supply it.

9679. (*Chairman.*) You cannot supply any name at present?—Yes, I can.

9680. You might do that now?—I can supply the names of the men at the discussion that took place at the Chelsea Clinical Society last year, I believe in March. Professor Wright, I believe, spoke against serum therapy to some extent.

9681. (*Sir William Church.*) Who is he?—Sir Almroth Wright.

9682. Where did he speak?—At a meeting of the Chelsea Clinical Society, and also Professor Hewlett. But, if I am asked to do it now I cannot do it with the same accuracy and care that I would if I supply a note of it. Then I believe Dr. Rosenbach, a German physician, has written against it, and Dr. Boucher, and Dr. Deswatines in France.

9683. I do not think it is any use mentioning the names here now, because what I have asked you to refer the Commission to is the names of persons of high professional and general repute who hold the view that you hold of the uselessness of antitoxin in diphtheria.

9684. (*Chairman.*) I should have thought it better, if you can mention them now, to do so, because if a note is sent in a list might be sent which we should have no opportunity of questioning as regards the eminence of the persons, and so forth. If you can give us any information now it would probably be more useful to us?—I could mention the name of one man of eminence who has previously expressed those views, but I believe I am precluded from mentioning his name at the present moment.

9685. (*Colonel Lockwood.*) Why?—I think it is one of the Commissioners whom I should mention.

9686. (*Chairman.*) You might as well let us have the name?—If I may mention Dr. George Wilson, I believe he has expressed such views; and Dr. Boucher, in France, the secretary of the French branch of the International Medical Anti-Vivisection Association, Dr. Lutaud, Pasteur's eminent opponent. From Germany I could supply names by the hundred.

9687. (*Sir William Church.*) We only want one, the most distinguished?—Dr. Lahmann, in Germany; and I do not know whether homeopaths in England would be considered to be men of repute or not, but I believe the homeopaths stand as one man against serum therapy. I can mention the hospital staff of the Homeopathic Hospital.

9688. If you had noted my question, I asked you for the names of those who have had large personal experience of the treatment of diphtheria, both before and after the introduction of antitoxin. People who have not had large experience of diphtheria both before and after the introduction of antitoxin I do not want you to refer us to, but I want you to refer us to those who have had large practical experience of the treatment of diphtheria both before and after the introduction of antitoxin?—That condition is scarcely a fair one to impose upon me, because the men who would oppose the use of diphtheria antitoxin would be men who oppose it on principle, and on various principles, and therefore would not try it; they would rather take the experience of other men who have failed than try it themselves.

9689. That is just what I want to avoid. Now one or two other questions, if I might be allowed to ask you. At Question 7423 I asked you a question about pithing: "You understand what pithing is? (A.) Yes, of course," and you have been kind enough to-day to give us a list of names of physiologists who use the term in various ways, you say; but do not they all use it in this sense, either that they mean total separation of the spinal cord from the brain or destruction of the cerebral hemispheres or of the whole brain?—I do not think they all use it in those senses. I have already given evidence to show the different senses in which it is being used.

9690. Yes, you have given us a number of names, and I ask you whether all those authorities to whom you have referred do not use the term either as expressing the severance of the spinal cord from the brain or the destruction of some part of the brain itself, either the cerebral hemispheres or the cerebral hemispheres and something more?—Then I must answer "No," because some people use it in the proper sense, the inclusive sense, the sense to which I would agree where the word pithing would be applicable—namely, the destruction of the brain and spinal cord.

9691. That is what I say?—No, I beg your pardon, I do not think you said that; you did not include the destruction of the spinal cord in your question.

9692. No, of course I exclude the spinal cord, that is going still further; but I say: Do any of the physiologists to whom you have referred us to-day make use of the term pithing in any other sense than either the separation of the spinal cord from the brain or the destruction of either the cerebral hemispheres or the cerebral hemispheres and other portions of the brain?—I am afraid I must give again the same answer, unless I misunderstand you entirely, that some use it in the real sense of destroying the spinal cord as well.

9693. I am perfectly well aware of that; that is a different question. I will not trouble you any more on that. I understood you to say, in answer to Dr. Gaskell, that you are of opinion that the spinal cord is sensitive to pain. I do not know whether the head also feels pain when it has been decapitated?—I think Sir Lauder Brunton gave some evidence to that effect about Ludwig holding that view. (Question 7106.)

9694. (*Sir William Collins.*) Do I rightly understand that the word "pithing" is ever used to denote the condition of mere separation of the brain from the

spinal cord?—A mere cutting—a mere cut, yes, it is used in that sense.

9695. That is one sense?—Yes, but it is very rare.

9696. Is it used in the sense of mere destruction of the contents of the cranial cavity?—Very often.

9697. That is another sense?—Yes.

9698. Is it used in the sense of destruction both of the contents of the cranial cavity and of the spinal canal?—It is used in that sense, too, and my contention is that that is the proper sense.

9699. Is it your opinion that only in the third and last sense the term pithing ought to be employed?—Yes, that is so.

9700. After I concluded my questions on the 1st of May you answered Question 7627 in these words: "From my own point of view I am prepared to say that nothing which I should call useful has been obtained by experiments on the lower animals"?—Yes.

9701. If that be so, should I correctly understand you to contest the assertion of those many witnesses who have appeared before us, who have stated that various drugs and other modes of treatment as well as other useful discoveries have been made by experiments upon the lower animals?—I answered partly in that answer that it was a question of relative terms, and that my personal opinion was that nothing indispensable or in the higher sense useful had been discovered by such means.

9702. Then in that sense anything useful could not have been gained by experimentation on the lower animals?—I look upon it from the moral point of view, and I do not believe that the lesser and immediate utility which might be claimed as the result of doing something against a moral law is of real advantage. I believe that it is a greater advantage on all planes, moral and physical, to do the thing which is morally right, and that it will ultimately also be found to have been intellectually right.

9703. To take the case of Dr. Cushny's evidence, would you contest the assertion that various soporifics, such as chloral and sulphonal, have been discovered by experimentation on the lower animals?—I should not contest that.

9704. Then do you contest that they are useful?—I contest that they could not have been discovered by experiments on human beings who offered themselves voluntarily. I contest that the method of experiments upon the lower animals is indispensable. From the experimental point of view they might just as well have been discovered by experiments on voluntary human beings who are anxious to find out the truth about a drug which they believe will be of value.

9705. When you say that they might have been so discovered, it is easy of retort that they might not; and it is alleged that as a matter of fact they were discovered by experiments upon animals?—As a matter of opinion I do not think that that answer could be given, because nobody could deny that they could have been discovered by a few experiments on voluntary human subjects, provided that the experimenters had been a little more unselfish.

9706. But you do not allege that they were not so discovered?—I do not contradict it.

9707. Then as regards local anæsthetics—cocaine, for example—do you say that that is not useful or that it was not discovered by experiments upon the lower animals?—I should say that cocaine is exceedingly useful.

9708. Do you say that it was not discovered by experiments upon animals?—I do not think I should say that; but I have the same answer to give in relation to that, that it might perfectly well and better have been demonstrated on the human being.

9709. Does the same answer apply to the case of nitrite of amyl, which has been frequently quoted in evidence?—I think it applies to all cases. If I were keenly interested in the testing of drugs I would certainly offer myself for testing them. I would not do it on dogs, cats, and rabbits.

9710. Whereas they might have been discovered by testing them on human beings, you do not deny that they were discovered by testing them on animals?—I do not deny that you can discover things by experiments on animals; I think I would be very foolish to attempt to deny it, you are bound to discover something. The question is, first, whether the discovery is really valuable; and, secondly, whether the discovery could not have been made through other means.

Miss L. Lindaf-Hageby.

5 June 1907.

9711. But when you make the statement that nothing which is useful has been obtained by experiments upon the lower animals, it seems to me that it is incumbent upon you to show, when it is alleged that anything useful has been so discovered, either that the thing is not useful or that it has not been so discovered?—Then I ought to have added, nothing useful which could not have been discovered by other means; because if an experiment be considered absolutely necessary, my contention is that it should not be a vivisection experiment on an unwilling victim.

9712. You also stated that you had been at the Pasteur Institute. The treatment of rabies or hydrophobia has been often alleged as an example of a useful discovery as the outcome of experiments on animals; have you anything to say in regard to that?—I have to say that I have seen long and sad lists published, amounting, I believe, to thousands of people, who have died in spite of the Pasteur treatment for hydrophobia. They are published in the "Annales de l'Institut Pasteur" and other journals.

9713. In that case do you allege that what has been discovered is not useful?—I am most strongly against the Pasteur treatment, certainly.

9714. (*Chairman.*) That is not quite an answer to say that you are against it; do you allege that it is not useful?—I do not consider it useful.

9715. (*Sir William Collins.*) In the case of drugs I understand you to say that nothing useful has been discovered by experiments on animals, although something might have been discovered by experiments on man?—Yes, the decisive experiment must be made on man.

9716. With regard to the treatment of hydrophobia, I understand you to say that it is not useful in itself?—Certainly.

9717. And with regard to the treatment of typhoid fever, plague, and cholera, do you say that useful things have not been discovered, or that they have not been discovered by experiments on animals?—In that case I should say that useful treatments have not been discovered by experiments on animals wherever the treatment takes the form of a serum.

9718. And with regard to snake poison, what answer do you make there?—I am not aware of any successful treatment that has been brought out for snake bites which necessitated experiments upon animals.

9719. With regard to the treatment of myxedema by thyroid extract, do you allege that the discovery is not useful or that it has not been made by experiments on animals?—I think that it has partly been made by experiments on animals, but the principle might just as well have been discovered by other experiments—in fact, an equivalent of thyroid extract is being made very largely, I understand, in chemical laboratories and prepared synthetically.

9720. As regards adrenalin as a mode of arresting hæmorrhage and for other purposes, do you allege that that is not a useful discovery or that it was not obtained by experiments upon animals?—I do not think that the use of adrenalin is absolutely necessary or that I should include it among that which is useful. That again is a matter of opinion whether it is useful or not. I do not consider it useful, if I answer the question plainly.

9721. In therapeutics adrenalin serves no useful purpose?—No, I consider that it is not useful.

9722. Do you think that it was discovered by experiments upon animals?—I am against all the organo therapeutic system of such drugs and the applying of drugs which is now in vogue.

9723. Do you contest the allegation that it was discovered by experiments upon animals?—I think it was discovered by experiments upon animals. A great number of experiments have been performed indeed in my presence with adrenalin.

9724. One more thing—the treatment of anthrax and the prevention of anthrax; do you think that something useful has been discovered there?—No, certainly not. I think there has been a great deal of failure. Only yesterday the papers contained an account of a new process which has been brought out by a technical chemist at Dewsbury, a purely chemical one, which promises much for the future.

Miss L. Lindaf-Hageby.

5 June 1907.

9725. (*Chairman.*) You prefer your judgment to that of Sir John Macfadyean, with his large experience upon a question of that kind, as to whether this treatment has been found a useful remedy for anthrax?—I have not heard his opinion.

9726. (*Colonel Lockwood.*) Would you not say that the discovery of the X Rays has done more for science than any discovery which has been made by the use of living animals?—I think there are infinite possibilities in the discovery of the X Rays, both for physiological investigation and the healing of disease; and in the light treatment and in all the new treatments, more than in any vivisectional treatment.

9727. And will be of more value than any results of vivisection?—Yes.

9728. (*Chairman.*) I think that concludes your evidence?—My Lord, I am not going to take up too much time of the Commission, but there are two things which I have not been allowed to answer; I will do it as shortly as I can—in five minutes.

9729. If you have not been allowed to answer I presume it was for some reason?—The first matter is with regard to a note that I was asked to supply on the paper by Dr. Brodie and Miss Cullis, and then I have an answer to Mr. Thane's statement about the dog that he referred to in his evidence on the fourth day, which is described in the "Shambles of Science"; and, thirdly, a few words about "the brown dog." There are two statements that I am very anxious to bring out on "the brown dog" in answer to Professor Starling and Mr. Thane.

9730. I hope you will give it very shortly, because these are matters which we have discussed at considerable length?—I will do it as shortly as I possibly can; I will only take a few minutes, and I will not read what I have got. The first note that I was asked to give is this: A further reference to the paper by Dr. Brodie and Miss Cullis to which I referred in my evidence shows that the animals were by no means pithed in the proper sense of the word, the spinal cord and the medulla oblongata having been left intact. Nor was it an immediately fatal operation, for such animals can breathe spontaneously and "survive for some four to eight hours." Artificial respiration was carried out during the actual experiments, not for the purpose of maintaining life, but in order to get a more uniform aeration of the blood. Then I have some comment upon that, which I do not think I will trouble the Commission with, but perhaps I may just mention what it is, as it is rather a question that touches the legal aspect of such a case. Either these animals are dead or are supposed to be dead, and then anybody can experiment upon dogs deprived of their brains—any man in the street; or they are alive, and then they ought to come under the Act. Miss Cullis, I see, had no licence when she performed these experiments, and I presume that she considers the animals to have been dead, and therefore that these were not illegal experiments. The question is of the utmost importance at the present moment, as the Act relates to experiments upon animals which are alive, and it seems that we must reconsider what it means to be alive. Then the point in Mr. Thane's evidence was in what he said at Question 1270. He said that the look of utmost agony in the eye of the fox-terrier was the result of our imagination, as "emotions are not expressed in the eye itself, but in the surrounding parts." In answer to this, I must point out that the "surrounding parts" of the eye were quite visible to us, and that it is immaterial to this particular case whether we prefer to localise the expressions of different emotions to the eye itself or its "surrounding parts." That is all I will trouble the Commission with on that point. I have now the last, and that is the so-called "brown dog." That was brought before the Commission several times, especially by Mr. Thane, at Questions 1551 to 1568, and by Professor Starling at Questions 3696 to 3705. I do not know that I shall be able to make myself intelligible now, as I leave out the greater part of my statement on this point; but there are principally two points of view that I wish to bring before the Commission; first, that Professor Starling has said before this Commission that this dog was "quite well" and "quite healthy," and that during the trial—in fact, the whole trial turned on that issue, which was presented by him and Mr. Bayliss—he said that it suffered from a disease, and its state was referred to as "morbid," and even the failure of the experiment was attributed by Mr. Bayliss to this "morbid" state. That is a contradiction to which I feel I ought to draw the attention of the Commission. Now comes the last, and then I have done, and that is that in operating upon this dog, in subjecting it to a third vivisection, a contravention of the Act was made, for the Act does not say that you are allowed to perform more vivisection experiments on an animal under Certificate B, provided that animal is still in a state of anæsthesia; the Act says nothing of the kind, it says that when the operator has finished, when his object has been attained, he is under an obligation to kill that animal. Now Professor Starling has acknowledged that he had attained his object with that dog, and yet he handed it over to Mr. Bayliss, and it is a significant fact that Mr. Thane, the Inspector under the Act, has told this Commission that he is not quite clear whether this is legal or not (Question 1558)—it is rather a "legal point," and, further, that he does not like it quite (now I may quote a word wrongly, because I do not read it), and that is not a thing one would desire to be done (Question 1561); and, further, that if there had not been this trial he would not have known of this procedure (Questions 1563 and 1564); and that, as far as he knows, there may be cases of a similar kind which would not appear in his report (Question 1563). Those things have been told to the Commission by Mr. Thane, and I have brought it in from the point of view of what has been said on the "brown dog" before the Commission.

9731. (*Sir William Church.*) With regard to the discrepancy between the statement that Professor Starling made here, that the dog was quite well and healthy, and the statement at the time of the trial that the dog was said to be in a diseased state, what was said to be the matter with the dog at the trial?—It was said to be suffering from chorea.

9732. Canine chorea?—Yes.

9733. What is that?—It is a disease.

9734. How does it manifest itself?—It manifests itself in twitching.

9735. And it was suggested at the trial, I think, that some of the movements which might be thought to be due to pain, and which moved the board, were due to this twitching of the muscles?—Quite so, that was the defence of Mr. Bayliss and Mr. Starling.

9736. What is the condition of a dog which has canine chorea?—I have seen a dog with it—Mr. Sewell showed it to me.

9737. What is its condition?—It is a dog that is in a state of disease. You cannot refer to it as being quite healthy.

9738. For instance, if it is a sporting dog is it able to be used for sport just the same as any other dog?—I should think not.

9739. You only think that?—I have seen a dog suffering from chorea, and I am sure that such a dog could not be used. That was not the "brown dog," for I do not admit that it had chorea—it was a bulldog.

9740. Speaking of dogs which have canine chorea, are they what you would call unhealthy; they have this twitching, but are they unhealthy?—The dog that I saw was diseased and in a very diseased condition.

9741. Was that the brown dog?—No.

9742. I am not saying that a dog might not be unhealthy?—I have seen a dog suffering from chorea at Mr. Sewell's establishment.

9743. Then you think I should not be speaking the truth if I told you that I had frequently shot over a dog which had twitchings?—That dog may have suffered from a very slight form of chorea, but, as I understand, it was inferred that the form of chorea that this brown dog was said to have suffered from, according to Mr. Bayliss and Professor Starling, was a severe form; but the dog I saw certainly could not have been used for sport; and what Professor Starling implied here before the Commission was that the dog had recovered from the operation, and that it was in the same condition as it was before the operation. He did not say that it had not canine chorea, but he said during the trial that it developed canine chorea, I believe after the first operation, between the first and the second.

9744. The dog had canine chorea before it was ever operated upon at all?—No, I do not think that was stated.

9745. I beg your pardon, it was?—I beg your pardon. I think Professor Starling stated distinctly

during the trial, and I think I know that trial, that he observed the chorea in January, and he had operated upon the dog in December—he performed the first operation in December.

9746. You assert that it was the result of the first operation?—I cannot assert that. I can only assert that it was declared to have come after the first operation.

9747. Of course we can ask Professor Starling himself, but that was not the case; it was not the result of the first operation. The dog had this twitching before ever it was operated upon at all?—That is not so according to Professor Starling's evidence at the trial.

9748. That I do not know anything about.

Miss L. Lindaf-Hageby.
5 June 1907.

9749. (*Chairman.*) It does not seem material to the question that we have to decide whether this operation upon the brown dog was an illegal operation or not?—I only brought it out as a contradiction on the part of Professor Starling.

9750. It is a contradiction that does not bear much on our particular inquiry; it may have done so on the trial; but you cannot ask us to disbelieve all Professor Starling's evidence, because you allege that there is a discrepancy between his saying that the dog was well and that the dog had chorea?—I think it is rather of some importance.

9751. I do not attach much importance to it myself.

TWENTY-SECOND DAY.

Wednesday, 12th June 1907.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).

Colonel The Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir J. McFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.B.
Captain C. BIGHAM, C.M.G. (*Secretary*).

Mr. (now Sir) HENRY R. SWANZY, F.R.C.S. (Ireland), called in; and Examined.

9752. (*Chairman.*) You are a Doctor of Medicine?—Yes, I am a Doctor of Medicine of the University of Dublin.

9753. And you are President, I think I am right in saying, of the Royal College of Surgeons in Ireland?—I am President of the Royal College of Surgeons, and I am sent as representing the College.

9754. Will you tell us, before you give us their message, a little about the Royal College of Surgeons in Ireland? It is a large body?—The Royal College of Surgeons in Ireland consists of a Body of Fellows; we have 466 Fellows, and we have also a large number of Licentiates—2,908 Licentiates. The Fellows elect the Council of the College, which consists of 19, and they also elect the President and Vice-President annually.

9755. Is it one of the qualifications that they should be practising in Ireland?—No, not at all. A great many of our Fellows practise in England and in the Colonies, and elsewhere—large numbers of them.

9756. But their headquarters are in Dublin?—Their headquarters are in Dublin.

9757. And you yourself, besides being President of the Royal College, are Ex-President of the Ophthalmological Society of the United Kingdom?—Yes.

9758. And Surgeon to the Royal Victoria Eye and Ear Hospital in Dublin?—Yes.

9759. And I presume from that that you are to a certain extent a specialist in regard to the eye?—I am.

9760. You are aware that we invited the Royal College of Surgeons in Ireland, to give evidence?—Yes.

9761. And it is in accordance with that request that you come here?—It is in accordance with that request.

9762. Would you just tell us what their views are generally on the question of experimentation on animals?—It is considered that it is necessary for the advancement of medical and surgical science, in that it has introduced great improvements and advance on our knowledge and our methods in the past, and that we may look forward to its doing similar work for the good of medicine and surgery and of humanity in general in the future. That is in a general way the position which the College takes up.

9763. Those are the views of the Council?—Those are the views of the Council.

9764. Which is the ordinary mouthpiece, I suppose, of the Body?—Yes.

9765. Is that the unanimous view of the Council?—Yes, that is the unanimous view of the Council.

Mr. (now *Sir*) *H. R. Swanzy,* P.R.C.S. (Ireland).
12 June 1907.

9766. And your own view?—And my own view, most distinctly; I should not have come unless I was prepared to back it up.

9767. As regards the use of anæsthetics and the avoidance of pain, have your Council expressed an opinion upon that subject?—Certainly. So far as it is possible, and so far as it is compatible with the success of the operations, it is necessary and desirable that every means should be adopted to prevent animals having pain, or inconvenience even, so far as it can be managed.

9768. You say so far as it is compatible with the success of the operation?—Yes.

9769. There are certain operations, as we know, which are provided for by the Act, in which the direction to kill the animal before it comes out of the anæsthesia is suspended?—Yes.

9770. What do you say to that provision; do you think that it is necessary?—Yes, certainly I do.

9771. And when you say, so far as is necessary for the success of the experiment, I suppose you are alluding to experiments of that nature?—Yes, the experiments are with the object of obtaining knowledge, and the animal should be protected from pain and inconvenience in so far as that is compatible with the obtaining of the knowledge which is proposed to be derived.

9772. Have your Council formed any opinion as to whether any animals which are now subjected occasionally, or frequently, to experiments should be excepted from the list?—It is held that there should be no exceptions from that list.

9773. That is to say, that the law should remain as it is at present?—Yes, there are no animals excepted now.

9774. There are exceptions. There is certainly exceptional treatment of horses, for example—of horses, dogs, and cats?—Yes; they require a special certificate; and there can be no objection to that; but some people propose that certain animals should be excepted, and that is what we do not agree with.

9775. That is what I understood, but I wished to have it quite clear whether you raised any objection to the present limitations as regards horses, dogs, and cats?—No, I do not think so.

9776. But you would not, as I understand, extend those limitations?—No, we would not extend those limitations.

9777. Then what do you say as to experiments upon

Mr. (now *Sir*) *H. R. Swanzy*, F.R.C.S. (Ireland).

12 June 1907.

animals for the purpose of enabling surgeons, or future surgeons, to acquire skill?—That is a point upon which I have heard opinions expressed; I have made it my business to inquire among general surgeons upon the subject, and perhaps when some general surgeons come before you you may get from them more direct information, because I am not a general surgeon, as you understand; but all those with whom I have spoken, including some of the most distinguished men with us, are clearly of opinion that it would be greatly to the advantage of surgeons, and of those learning to be surgeons, if operations upon animals for the purpose of acquiring skill were permitted.

9778. Would you apply that to students, or only to those who have taken degrees or already acquired and given proof of having acquired a certain amount of skill?—I would extend it to students towards the end of their course, when they were almost surgeons, and when they were about to enter upon practice, where they would have to perform operations very soon upon the human animal.

9779. Would you have surgeons who were permitted to experiment for those purposes do so under a special licence for the purpose, or would you let it be one of the incidents of their being qualified surgeons?—I presume that it would require a special licence in this way: That the animals ought to be protected from pain and inconvenience as much in operations for skill as in operations for the ascertaining simply of knowledge; and therefore I presume it would be necessary to have a special certificate. But that is a point I have not considered; I am merely speaking in a general way.

9780. You mean that you would apply all the protections which are applied to animals as to freedom from pain to the cases of those who were experimented upon for the purpose of acquiring skill?—Yes, I would protect animals to the utmost in that case, as I would also in the case of experiments for obtaining knowledge.

9781. But I was rather asking you, would you require a person who was to get leave to experiment for purposes of that sort to have a special licence or certificate for that purpose from some authority?—I suppose it would be necessary.

9782. (*Sir Mackenzie Chalmers.*) It would not be allowed under the existing law at all; therefore it would be a change in the law?—I do not know what measures would be necessary, but in a general way it is held that it would be a most desirable alteration in the law if it were permitted.

9783. (*Chairman.*) You have not considered the question whether the authority to grant such a licence should be the Home Office or a medical authority, or both?—No, I have not at all.

9784. But you think that the law should permit experiments to persons having certain qualifications already for it?—Yes, I do. I agree with a witness who was here—I forget now who it was—who made a very striking observation, which was that he regarded the present law as immoral, because it did not permit these operations upon animals for the acquirement of skill.

9785. (*Colonel Lockwood.*) Was he a medical witness?—He was a physiologist.

9786. (*Dr. Wilson.*) It was Professor Starling?—Yes, Professor Starling. He said that he regarded the present law as immoral, because it did not permit operations for the acquirement of skill.

9787. (*Chairman.*) Because it sent out persons as being qualified for surgery who had not had an opportunity of acquiring that skill?—Yes, because it excluded animals from being used for the purpose of obtaining skill.

9788. Then another point upon which we have had a great deal of difference of opinion from witnesses before us is as to whether experiments should be permitted for the purpose of teaching students by demonstration. What is the view of your Council and yourself with regard to that?—The view of my Council is that it is desirable that students should be taught when necessary by means of experiments upon animals. There was one member of our Council—I wish to be perfectly candid—who seemed to be a little doubtful on this subject; but he seems to have altered his mind about it.

9789. I asked you whether that was the view of your Council and yourself. Did you agree with the majority of the Council, or did you agree with the doubts of the other gentlemen?—I agree with the majority of the Council.

9790. Have you considered at all the question of what limits, if any, you would put upon demonstrations to students, or would you leave the law as it is?—I would not limit it any more than it is limited.

9791. So much as to the general views. You have told us that your practice and experience lie principally in matters of eye disease?—Yes.

9792. And I think you wish to illustrate your views about the value of experiments upon animals from your experience in eye treatment?—I should like to endeavour to do that if you will allow me.

9793. If you please?—Of course, the question of inflammation, and what inflammation is, has been one of the most important questions, upon which a great deal of light has been thrown within the last 50 years or so, and some of the pioneer knowledge in this matter was gained by experiments upon the eyes of animals. The cornea of the eye is peculiarly suited for observing the processes of inflammation going on, as shown by the experiments of Cohnheim and Leber. Cohnheim was one of the first who showed what pus was, and a great deal of his experiments were made upon the cornea of animals.

9794. Of living animals?—Of living animals. Experiments on the origin of pus corpuscles.

9795. Was that before the days of anæsthetics?—These experiments were done in Germany, and they were not probably quite so particular there. I do not advocate some of the methods which have been used there, but these experiments would be done under anæsthetics, the animal would be anæsthetised, of course, during the whole time, and then not killed afterwards, because you could not see what went on afterwards unless you allowed the animal to live.

9796. These are German experiments that you are speaking of?—They are.

9797. Merely for the purpose of giving us the history?—I am only giving you the history. I want to point out in what way, by experiments upon animals, we have gained knowledge concerning inflammation which is of the utmost importance to medicine and surgery in general. Other cases which I have to bring forward are more specially connected with disease of the eye; but that is a general question, and a most important one, a great deal of knowledge of which has been obtained by experiments on animals' eyes.

9798. That is to say, the discovery of what pus is and how it is formed?—Yes.

9799. What would be about the date of those experiments?—Cohnheim was in 1873, perhaps rather earlier. His first work was published in 1867, but he wrote a monograph in 1873 on the subject. I was in Berlin myself at the time, and I saw his experiments, not upon animals' eyes, as it happened, because his very earliest experiments were done upon the mesentery of frogs and the tongues of frogs, and I saw those. Then as regards the function of the ciliary body, it is very important to know what the function of the ciliary body is.

9800. Will you explain to us what is the ciliary body?—I will try to do so. The iris is the part of the eye which gives colour, when a person has a blue eye or a brown eye, and that is the only part of a certain coat of the eye that one can see. There are two other parts, the ciliary body and the choroid.

9801. Are those two films, as it were, under the colouring one?—Yes, they are behind the white of the eye. The iris you can see in front through the cornea. It was not known what part of this uveal tract, whether the whole of it or what parts of it, secreted the fluids of the interior of the eye; there are two fluids, the vitreous humour and the aqueous humour. We knew pretty well, or suspected, at any rate, that these fluids come from the uveal tract, or from some part of it, but it was not until the year 1880 that it was definitely ascertained that the ciliary body was the part of the eye which secreted these fluids, and then we immediately began to understand certain diseases of these two fluids.

9802. Were those fluids discovered by experiments?—No, they were always known, I suppose, from any remote period. When we found that it was the ciliary body which secreted these fluids—and that discovery was made by experiments upon animals—we then began to understand certain diseases of the eye which we had not understood the nature of at all before. There was

one disease of the eye which was called keratitis punctata, which we thought was a disease of the cornea; but from the time when we ascertained the meaning of the ciliary body we learned that this keratitis punctata was merely a symptom of inflammation of the ciliary body, and consequently we then went about treating the keratitis punctata in quite a different light. Then, also, there are opacities in the vitreous humour, which sometimes appear, and one wondered what they meant; and there were various ideas as to what they meant. We now know that for the most part these opacities, too, are due to inflammatory processes in the ciliary body, and consequently we now proceed to deal with them in a different way.

9803. About when would that discovery be made?—That discovery was made definitely by Deutschmann in 1880.

9804. You say it was discovered by experiments upon animals; was it discovered wholly by that, or was it assisted by clinical observation or by observations on the human eye in cases of disease?—It was discovered entirely by experiments on animals. There was no other way by which it could be done.

9805. You have something to tell us, I think, about the corneal endothelium?—The cornea is the clear part of the eye which covers the iris, between you and the iris; if you look at somebody else you see yourself in that person's cornea—it is the glittering, bright part of the eye. On the back of the cornea there is a very delicate membrane called the endothelium, and between the cornea and the iris there is a little water called the aqueous humour, of which I have already spoken. We did not know what use the endothelium was, but it was discovered by Leber in the year 1873 that the use of the endothelium is to protect the cornea from the aqueous humour—to prevent the aqueous humour filtering into the cornea. If the endothelium is damaged or injured the aqueous humour percolates into the cornea and makes the cornea opaque; and, of course, opacity of the cornea interferes with vision. That has been a most important discovery, because now when we are operating we are most careful to avoid injuring the endothelium, for if we injure it—suppose that in extracting a cataract by any chance we injure the endothelium either with our instruments or by using some antiseptic, a weak sublimate lotion getting into the anterior chamber and injuring the endothelium—the aqueous humour percolates into the cornea and makes it opaque.

9806. That might produce total blindness, I suppose?—At any rate, it would make the eye a very imperfect eye, a useless eye, and damage the sight. That is knowledge which we could not possibly have gained in any way except by experiments on animals. Previously we used sometimes after operations to have opacity of the cornea; and we did not know why it happened. Now we not only know why it happens, but we know what we should do to prevent its occurring. I have seen this thing happen myself and I did not know why it happened. It does not occur now with me, because I carefully avoid those things which would produce it.

9807. By experienced oculists I presume that is perfectly understood, and those effects are avoided now?—Yes, certainly.

9808. Could you explain any further why experiments on animals were essential to this discovery?—I am at a loss to understand how it could be ascertained in any other way.

9809. You say that it was ascertained, in fact, by that means?—Yes.

9810. You gave us the name of the experimenter?—Leber.

9811. In what country was it?—In Germany.

9812. Has he published accounts of his experiments?—Yes.

9813. I am not asking you to give them, but I suppose you would give the same answer here as you gave as regards the function of the ciliary body, that mere clinical observation could not have discovered it?—It could not have discovered it. One might have guessed, but guessing is not any use; we must have definite absolute, downright knowledge.

9814. What would be the nature of the experiment for making this discovery as regards the corneal endothelium?—There were a series of experiments, of course, but the one which was conclusive, or, at least, one of those which was fairly conclusive, was that an incision was made in the cornea, a sharp instrument was passed into the anterior chamber of the eye, and the back of the cornea was deliberately injured—in fact, it was injured in the form of a cross; then the little wound in the cornea healed, the aqueous humour re-formed after a few hours, and soon one saw in the cornea a little grey cross corresponding with the injury which was done on the back of the cornea; so that obviously the condition of opacity in the cornea must have arisen from the wound or injury on the back of the cornea.

Mr. (now Sir) H. R. Swanzy, F.R.C.S. (Ireland).

12 June 1907.

9815. As you say, that is only an illustration of the kind of experiments. I suppose there were a series of them?—Yes, no doubt.

9816. Then you wish to deal with transplantation of the cornea?—As I have just been saying, the healthy cornea is clear, and when opaque it interferes with vision. A great many diseases cause opacity of the cornea, whilst the rest of the eye is perfectly good for vision, so that if there were only a clear cornea the patient would be able to see very nicely. For probably fully a century or more there have been attempts made to transplant a clear cornea from the animal's eye to the human eye in such cases, with the object of providing the patient with a clear cornea and good vision. Those experiments began so long ago as the year 1831; at any rate, Reisinger in the year 1831 operated and used a rabbit's cornea for the purpose. He wanted to transplant the whole cornea from a rabbit; he took away the opaque human cornea and took the rabbit's clear cornea, and put it on instead, and healed it on, but it soon became opaque. Stilling, in 1833, tried the same thing, and there were a great many other experiments of that sort, modified by different people as they tried to think out what could be the reason of the transplanted cornea becoming opaque; but always, although it healed on, it became opaque, so that the operation was no use. Although it healed on there it became opaque. I have not thought it necessary to bring every name here; but, at any rate, it was early in the last century that those experiments began. The question seems to have been taken up again in 1872 by Mr. Henry Power, who still lives, although he does not practice in London any more, who read a paper at the Ophthalmological Congress in London that year. He had been making experiments upon dogs and cats and rabbits, with the object of discovering a good method, and he, too, found that although he could do the operation successfully, yet, when the cornea had healed on, it always became opaque. That was the great trouble, that although you could do a successful operation as such, yet the new cornea always became opaque.

9817. You mean by successful operation, one in which the human being adopted the transplanted cornea?—Yes, a surgical success, but not a success in giving the patient any advantage. Therefore the great puzzle was to do this operation in such a way that the cornea would not become opaque; and the knowledge that was gained by Leber's experiments, which showed that it was the endothelium on the back of the cornea which protected the cornea from the aqueous humour, and that when the aqueous humour percolated into the cornea the cornea became opaque; it was that knowledge which helped us to transplant the cornea from a rabbit or from a freshly enucleated human eye on to another human eye with retention of its transparencies. What was done was then the opacity was trephined off down to a certain depth and the posterior layer of the cornea and the endothelium were retained, and then a piece of the same size was taken off the other cornea with the same trephine, and put into the little hole in the cornea, where it healed on and it remained clear. This was first done by Von Hippel in the year 1877.

9818. What does trephining there mean?—The little trephine is a little circular knife—a little punch, you might say almost. A piece was punched out of the opaque corner and a piece of the same size punched out of the clear cornea, and the clear cornea put on to the opaque cornea, and then, in consequence of the endothelium on the back of the cornea not having been interfered with, as it was in previous attempts, the new clear flap that was put on remained clear. I do not say that that is an operation which is in every-day use; it does not happen in many cases that you can do it, because, unfortunately, there are not a very large number of cases where the cornea is not opaque right through. If it be opaque right through there is no use in taking away a piece of its surface, and the operation is only good

Mr. (now *Sir*) *H. R. Swanzy*, F.R.C.S. (Ireland).

12 June 1907.

for cases where the opacity does not go right through the whole thickness of the cornea; there is that limitation to it. But I give it as an example of the valuable progress made in surgery for the good of people who suffer from blindness of a certain kind, and as the result of knowledge gained by an experiment upon an animal. It was the same experiment, in fact, which I referred to before as so useful in letting us know that we must not injure the back of the cornea in operations.

9819. Has serum therapy been utilised for diseases of the eye?—Yes, we are beginning now to use it a good deal. I have put down in my *précis*, as my fifth item, serum therapy; but I would ask you to take that number along with No. 7 and No. 14, because they really are all more or less serum therapy. There is an ulcer of the cornea which is called ulcus serpens. It is an exceedingly severe form of ulceration, and eyes are very frequently lost by it; at any rate, if they are not lost as eyes, they are lost as seeing organs, because it causes opacity of the cornea; it is one of the diseases of the eye which causes severe opacity of the cornea. Our methods hitherto have been unsatisfactory; except in the mildest cases we are seldom enabled properly to save the sight of an eye in this disease. The organism which causes this ulceration is the pneumococcus, and recently a pneumococcus serum has been prepared by Römer, which has been used for treating this disease; at any rate, it ameliorates its severity to such an extent very often that it enables the other measures which we have been hitherto using to be used with greater benefit. The experiments were first made upon rabbits by Römer. That is a recent thing—1905 is the date of it. Then with regard to tubercle of the eye, which is a very prevalent and very devastating disease of the eye, we find that treatment with tuberculin is exceedingly valuable. It is useful both in treatment and in the diagnosis, because, although it is a common disease and in many instances you can diagnose it perfectly well, and anyone seeing it is able to make a diagnosis at once, yet there are cases where one is in very considerable doubt, and you have to resort to other measures than your knowledge of appearances; and by using tuberculin in a rather high dose you get certain reactions which help you to make the diagnosis. There is also a method of diagnosis which is not possible in this country at present in the ordinary way in hospitals, but which can be done, I suppose, if we get some friendly physiologist to help us, namely, if we take a little of the water out of the aqueous humour in a case where tubercular disease is suspected and introduce it into an animal's eye, say, a rabbit's eye, it produces tuberculosis of the eye if the disease which the patient is suffering from is tubercular.

9820. That would be for the purpose of discovering whether the tubercle was present in the eye of the human being?—Yes. The method of treatment of diseases of the eye with tuberculin was introduced by Von Hippel in 1904. There is another instance, No. 14 in my *précis*, which refers to a very valuable remedy called jequirity. Jequirity is the active principle of the paternoster bean, a Brazilian seed. We have in these countries, especially in Ireland, a great deal of a disease called trachoma, which is a most destructive disease to the eye. In some cases it quite blinds people, and in order to cure it we have many remedies; but one of the most valuable is this jequirity. It is in my experience a most valuable remedy, but there is one drawback to it, and that is that sometimes the reaction which it causes gives rise to a danger in the eye; it acts in some people with such violence that it endangers the cornea; and therefore we would like very much to have some means of controlling its action. It was found by Ehrlich that it was possible to immunise animals from jequirity. He devised or discovered, I do not know which word to apply, an antitoxic serum which, when introduced into the animal, absolutely prevents your being able to produce a jequirity reaction in its eye at all. Then further experiments by Römer elaborated this point, and Römer found that in human beings if this serum was introduced into the blood the individual became immunised, and that you could not produce jequirity reaction in the eye; and, further, that even if the serum was dropped into the eye without being introduced into the general system, it would prevent the patient getting a jequirity reaction; and, again, if the individual has a very violent reaction from the jequirity and you want to moderate it, you can do so by dropping the serum into the eye. It is therefore really a very valuable remedy in that way.

9821. What is jequirity; is it a drug?—Yes, it is a drug; it is a little black bean with red spots; it is called the paternoster bean; it comes from Brazil.

9822. I think we have had some evidence that it was used simply in the ground bean?—That is true. What is done is, the skin is peeled off, and then the bean is pounded up, and you make an infusion of it, and it is this infusion which is applied to the conjunctiva, the lining of the eyelids.

9823. I think we had one case given to us where the dry jequirity itself was said to have been rubbed into part of the eye?—I suppose that probably the dry preparation would do, but clinically I always use the infusion.

9824. It was not an experiment in England; it was an experiment, if I recollect rightly, in Canada; in some place, at any rate, where our present law as regards vivisection does not apply?—No doubt.

9825. (*Sir Mackenzie Chalmers.*) Does the injection cause great pain?—In the human eye, yes, it is very painful; the temperature goes up, and there is considerable feverish reaction in the individual.

9826. When it is used as a remedy?—When it is used as a remedy.

9827. Still, the result is worth it?—Oh, yes, it is well worth it.

9828. (*Dr. Wilson.*) It is to allay that pain that the serum is given?—Of course, the serum would allay the pain, no doubt, but that is not the great object. Unfortunately, jequirity, when it gives rise to a violent reaction, may produce ulceration of the cornea. That is the danger of it.

9829. Is this serum used in Ireland?—No, we have not got it yet; it is not very easy to get.

9830. You have no personal experience of it?—I do not think you could get it in this country at all.

9831. (*Chairman.*) There are some other experiences of yours that you wish to give us. Sympathetic ophthalmitis is one, I think?—Yes, sympathetic ophthalmitis is a very important disease. As you know, when one eye is injured the other eye, in certain kinds of injuries, is liable to become very seriously inflamed, and both eyes may be lost. It has been the object of oculists and pathologists for many long years to ascertain what this sympathetic ophthalmitis is and how it comes about. It is, I think, an example, perhaps, of experiments which, while their results were negative, yet had their use; because I think it is a greatly mistaken idea in some people's minds, that when experiments are made and fail to prove what is wanted to be proved, the experiments have been thrown away. But really that is a wrong point of view. If an experiment fails, or a series of experiments, then it is shown that that, at any rate, is not the meaning of the thing, and that we must try in some other direction. Sympathetic ophthalmitis, it was thought at one time, was caused by the irritation of the nerves in one eye giving rise to irritation of the nerves in the other eye, and that then, as the result of irritation merely, inflammation resulted, just the same as when you get a foreign body into one eye the other eye waters very much. But this was found not to be so. Experiments upon animals were done with the object of deciding this point, too; I cannot really give the details, because it is a long time ago now. Then there was an idea that the inflammation, the bacteria or the toxins, travelled round from one eye through the optic nerve of that eye, across the structure we call the optic commissure, down the optic nerve of the other eye and into that eye, and then set up the inflammation in the latter. Many experiments were made in this direction with the object of finding that out; and, of course, the reason why so many experiments were made was because one man made an experiment and he used a certain kind of infection, and that infection did not answer, and then somebody else used another kind of infection, and so on, and the experiments were not all carried out exactly in the same way, or there would not have been any use in repeating them; they were all done in different ways by different men in the course of years, and they all failed to show that the inflammatory process extended round from one eye to the other through the optic nerve and commissure. Now we have begun again in recent years, largely by reason of the generally held

view of the infection of the blood in disease which we have nowadays; and the idea now is that sympathetic ophthalmitis comes about really as a metatastic disease; that is to say, when one eye is injured micro-organisms set up their residence in it, and in the course of time—a few weeks— they extend into the general system; but they do no harm to any organ in the general system except the second eye if they happen to go into it; and they appear to have some special attraction for the other eye, which is a very remarkable thing. If we knew for certain that this view were correct, and if we knew, which we do not yet know, what the specific micro-organism is, we could then perhaps get a serum which, when an eye was injured, we could introduce into the patient's system and immunise him and prevent him from getting sympathetic ophthalmitis. And many a person who is going about blind now, if we had such knowledge, would now be seeing.

9832. It is a very common disease, is it not?—It is a very common disease; it occurs in shooting accidents and all kinds of perforating wounds; we see it every day. The best thing we can do for people nowadays when they come to us with an injured eye, is to advise them to have it removed. But very frequently they say that they would rather not; and they go off and come back again in a few weeks with serious inflammation in the other eye; and they go about with the help of a dog and a stick for the rest of their lives.

9833. Does taking the other eye out prevent it?—Yes, it does, because it takes away the primary focus where the poisonous toxins and the poisonous bacteria develop.

9834. That is a case in which many experiments have been made with a view to discovering a remedy, but they have none of them been successful?—That is an example of a disease in which for years and years experiments were made in one direction, because it seemed so probable that the disease extended round from one eye to the other; and those experiments all resulted in a negative way. Now the new light which has been thrown upon general pathology, and so on, has led us to direct a great deal more attention to this other way of infection of the second eye; and it is by experiments upon animals that this other theory must be followed out and shown whether it is right or wrong.

9835. But all that has been done at the present time has been to narrow the field of research to show that certain fields of research are useless?—Yes; efforts are being made to prove or disprove this theory.

9836. Is glaucoma another case in which experiments on animals have been of use?—Yes, glaucoma is a very prevalent disease and a very serious one. The nature of glaucoma is that the eyeball gets too full. When there are just enough of the fluids within the eye and not too much, they keep the eyeball at a certain tension, and if you put your finger upon your eye you can feel that it is slightly soft. In glaucoma the eyeball gets so full that if you put your finger on such an eyeball it feels as hard as a marble; in fact, the intra-ocular pressure is greatly increased. The idea at first was that there was too much fluid secreted, that glaucoma was a disease of hyper-secretion; or, perhaps, if there was a low form of inflammation, it was the fluids given out by inflammation which caused the increased tension. Von Graefe, about the year 1867, discovered a cure for glaucoma, and he discovered this cure, not by experiments upon animals, but by clinical observation, because, after all, every advance that we make is not made by experiments on animals. Although experiments on animals teach us a vast deal, yet other methods are also not forgotten; and it was by means of clinical observation that Von Graefe, about the year 1867, discovered that iridectomy cured glaucoma (iridectomy is taking away a little piece of the iris), and the way in which it acted, he thought, was because it took away a little piece of the secreting surface of the eye; because at that time we did not know, as we know now, that it is the ciliary processes which secrete the intra-ocular fluids, and it was thought that it was by reducing the amount of the secreting surface within the eye that the tension of the eyeball was reduced. Deutschmann's experiments showed, of course, that the iris secreted very little, but the ciliary process secreted the main portion of it. But it was in the year 1873 (and to this I particularly wish to draw attention) that Leber discovered, by experiments on animals, that the way of exit of the intra-ocular fluids was at the angle of the anterior chamber, the part that we call the ligamentum pectinatum; and he discovered that this is where the intra-ocular fluids make their escape; because in our eyes, normally, these intra-ocular fluids are always being secreted, and they must be also getting away, or the eyeball would become too full. It is obvious that they must be getting away at the same rate as they are being secreted; and fresh fluids being secreted, when they become used, are discharged from the eye, and the place where they are discharged is the angle of the anterior chamber, as Leber pointed out in the year 1873. A few years after that it was discovered that in the glaucomatous eyes of individuals, which had been removed for one reason or other, the angle of the anterior chamber was blocked, and then it became at once plain that it was the blocking of the way of exit of the intra-ocular fluids which caused glaucoma, and that therefore it was not a disease of secretion, as was formerly thought, but a disease of retention.

Mr. (now *Sir*) *H. R. Swanzy*, F.R.C.S. (Ireland).

12 June 1907.

9837. Do these fluids escape, then, at the surface of the eye?—They do practically escape at the surface of the eye.

9838. (*Colonel Lockwood.*) Can you cure glaucoma now?—Yes. I was just going to talk about that. The cure of glaucoma previously had been, and continues still, for the matter of that, to be mainly iridectomy, but, as I said before, it was thought that the way iridectomy acted was in consequence of taking away the little piece of the iris. Now that we know that this is not the way the operation acts, and that it is by freeing the angle of the anterior chamber, we make an incision into that very angle, and we know that we must make this incision in a certain way; for it is not the taking away of a piece of the iris that is the important part of the operation, but it is the incision, and the way in which the incision was made. This discovery of the blocking of the anterior chamber as being the cause of glaucoma, which followed on the knowledge that that was the way of the fluids escaping has led also to the use of a very important remedy, or, at any rate, a palliative, in these cases—that is eserin, the active principle of the Calabar bean. Eserin contracts the pupil. It was immediately thought that if the angle of the anterior chamber is blocked, then if you put eserin into the eye, and contract the pupil, that will drag away the root of the iris from the angle of the anterior chamber, and in that way free the angle of the anterior chamber, and then the fluids will be able to get out again instead of being pent up in the eye. And this is a remedy which we use very much. It can hardly be called a remedy, but, at any rate, it postpones the evil day ,and it is a very great aid in many cases.

9839. (*Chairman.*) Is it used successfully?—Yes, successfully. The use of eserin in contracting the pupil was discovered by Fraser, of Edinburgh. I do not know how long ago, but, at any rate, it, too, was discovered by experiments upon animals. So that here you have a number of experiments upon animals all bearing towards the cure or alleviation and understanding of one very important disease of the eye. I might say perhaps that in this country very important work has been done by Parsons, Henderson, Starling, and Paterson regarding the normal secretion and excretion of the eye; that is the branch of knowledge improvements in which led us to understand so much about glaucoma.

9840. Were those experiments of pure research, or were they addressed particularly to the cure of glaucoma?—For the most part they were experiments of pure research. Those I spoke of, by which Leber discovered the way of exit at the angle of the anterior chamber, were pure research experiments.

9841. Then I see that you propose to make some observations on two diseases, namely, cataract and detachment of the retina?—Of course, it would be very desirable to know the cause of cataract—senile cataract; and investigations by experiments upon animals are now being made on this subject. Römer has investigated the question of lentotoxins, or cytotoxins, and the protection of the lens against them in normal conditions. Hess's experiments lead him to suspect that the cause of cataract is some auto-intoxication. These are quite new; they are going on now, in fact. Römer's experiments were published in the 60th volume of von Graefe's Archives, and that is quite a

Mr. (now *Sir*) *H. R. Swanzy*, F.R.C.S. (Ireland).

12 June 1907.

recent volume; but I mention these experiments because they are quite new; and they have not resulted yet in anything, but there is every reason to think that we will gain knowledge, and the experiments have to be continued. Detachment of the retina is also a very serious disease of the eye. The retina becomes separated off from the choroid coat of the eye by the intervention of fluid between the two. It was discovered by Leber in 1882 that the primary cause of detachment of the retina is shrinking of the vitreous humour. The disease is an exceedingly difficult one to treat; it is one of the most hopeless that we have, and attempts are being made to replenish the vitreous humour, by introducing the vitreous humour from animals, and some of those cases have resulted with advantage.

9842. As regards the next three matters—cocaine, adrenalin, and argyrol—I think we have had a great deal of evidence upon that class of subject, and unless you think there is anything very special regarding them, we need not perhaps go into them in detail?—I do not think that I need trouble you in that case.

9843. (*Sir Mackenzie Chalmers.*) We have not heard, I think, before of argyrol?—Argyrol is a preparation of silver, and it is used very largely for external diseases of the eye—diseases of the conjunctiva.

9844. Has animal experimentation had anything to do with it?—Yes.

9845. (*Chairman.*) You might tell us about it?—Experiments upon rabbits showed that when argyrol was introduced into the anterior chamber of a rabbit's eye it did no harm; it did not set up any inflammation or anything of that sort; and as it was known that it was good for certain bacterial diseases of the conjunctiva, a friend of mine, Dr. Mooney—one of the junior surgeons in the hospital that I belong to in Dublin—thought he would try what good it would do in a very severe case of inflammation extending into the interior of the eye in a case of injury, and he introduced in this almost hopeless case some drops of argyrol into the anterior chamber, with the result that in the course of twenty-four hours the eye was a great deal better, and in the course of twenty-four hours more was quite well. I regard that as a very brilliant result from the use of a remedy which had never been used in that way before, and which he would not have used if he had not learnt that it, when introduced into a rabbit's eye, did no harm there.

9846. It was a painless experiment on the rabbit, I presume?—I suppose so. I cannot give details. Dr. Mooney had read of it somewhere, and I asked him before I came away where he had read it, and he said he would look it up and tell me, but he had not done so before I came away.

9847. It does not bear so much upon the question of painful experiments on animals?—No.

9848. (*Sir Mackenzie Chalmers.*) But he dared not have used it if it had not been for experiments on animals?—No.

9849. (*Chairman.*) But it does not seem to involve anything in the nature of an experiment. What have you to say with regard to the Finsen light?—The Finsen light, as you know, is a very valuable remedy in certain serious superficial cancers, lupus, and so on; it is a bacteriacide in those cases, and it seemed that it might be useful in certain bacterial diseases of the eye. But the Finsen light, as used in the usual way for lupus, could not possibly be used for the human eye, because it would do it a great deal of harm. The eye has to be carefully protected in using the Finsen light, I believe, for lupus of the face. Yet it seemed so likely that it might be of use if its intensity could be subdued, that experiments were made in the first place to see if it would kill any of the bacteria that infect the human eye (there would not be any use in using it if it did not), such as the streptococcus, the pneumococcus, and so on. Hertel has tried upon animals' eyes whether it would kill these bacteria if used in a modified form.

9850. Without destroying the eye?—Without destroying the eye; and he has found that that can be done; consequently, perhaps, we will come to use it in this modified way for the human eye.

9851. That, I suppose, is a thing which would involve, in perfecting experience, painful experiments on a certain number of animals?—Certainly, because you must infect the animals' eyes with these bacteria in order to perform the experiments.

9852. That is a case of painful experiments which have had some useful result?—Yes, which promises to have some useful result.

9853. (*Colonel Lockwood.*) You hold, of course, your own opinion on this subject of painful experiments on living animals, apart from that held by your Council, naturally?—Yes.

9854. Do you trace your own success as an eye specialist entirely, or the greater part of it, to experiments made on living animals?—A great deal of it.

9855. Did you witness many experiments?—No, I did not.

9856. Or did you conduct yourself any experiments?—No; I am a practitioner; I merely utilise in practice the knowledge which is gained by these experiments.

9857. It was more from what you read of experiments than from anything you witnessed yourself?—Certainly. It is not necessary to witness them in order to know how to utilise the results obtained from them.

9858. You think that reading about an experiment is quite as useful to the profession as witnessing experiments?—I do not know quite what sort of experiments you mean.

9859. Experiments upon living animals?—The experiments I have spoken of here have been for the most part pathological. There were some, as the meaning of the endothelium on the back of the cornea, and the use of the ciliary body, which were physiological. But I think, of course, that it is not necessary that in every discovery in physiology which is made by means of experiments upon animals those experiments should be always seen by every person who is a doctor; that would be quite impossible.

9860. I understood you to say that you were in favour of demonstrating to students by means of experiments on living animals?—Yes, certainly.

9861. And you would be sorry to see them put a stop to?—I would, indeed.

9862. Do not you think that that knowledge could be arrived at, as it was in your own case, as much by reading as by witnessing experiments?—The experiments which are shown to students relate to the great functions of the body, some of the greater functions of the body, such as the action of the heart, peristalsis of the bowels, and such things as that. They certainly are things which ought to be taught to students in the most demonstrative manner possible.

9863. But I may take it, indeed, it is well known, that you yourself have arrived at considerable eminence in your profession, and yet you say you have witnessed no experiments?—It would have been a very good thing for me if I had.

9864. You think you would have been a still greater man?—I am sorry I did not see still more of them.

9865. Did you see any in Germany?—I saw the beginning of Cohnheim's experiments, and they certainly were something which impressed the nature of inflammation upon my mind more than anything I ever saw in my life. I only wish I had seen more. When I was a student these things were not to be seen, and therefore, of course, I was at a disadvantage.

9866. You said, of course, that you were, and I take it naturally that you are, anxious that the animals during these operations should be insensible to pain?—Yes.

9867. But you rather qualified that statement, because you said it must be consistent with the success of the operation?—Yes, that is, within the four corners of the present Act of Parliament.

9868. Therefore I take it—I do not want to put an unfair question—that your view is that the success of the experiment on the animal is of more value than that the animal should not suffer pain?—Yes, I do most distinctly think so.

9869. And you also think that these operations which you have described to us as being very successful, and which have been derived from experiments on living animals, could not have been arrived at by any clinical examination?—No, I cannot imagine them to have been arrived at by any clinical examination.

9870. Or by any operation on a dead body?—No, oh, no, certainly not.

9871. Only and solely by experiments on living animals?—Certainly.

9872. You did, I know, and very rightly, draw our attention to the fact that the use of iridectomy in glaucoma was by Von Graefe stated to have been not discovered by experiments on animals?—Yes.

9873. Which do you consider, if it is a right question to ask you, are the most skilful operators on the eye, the Germans or ourselves. I do not wish to press it. Would you say that on the whole we are on a par with the Germans. You understand why I ask the question, of course?—I cannot imagine why you ask it.

9874. I will tell you why. Because what I am going to suggest to you is that the Germans are under no restrictions, and we ourselves are under very strong restrictions; and if we are equally as good as the Germans, these restrictions on experiments on animals have not been hurtful?—But are you asking me this with regard to what I suggested, that surgeons should be permitted to operate on animals for the purpose of obtaining skill?

9875. Partly that; but partly I want to know this: Do you think that the regulations laid down by the Home Office to prevent suffering in animals have hampered our science in England?—Well, I really do not think I can say that they have. I think that they are sufficient, except in regard to that one restriction, that our surgeons should be allowed to operate for the purpose of obtaining skill.

9876. But under licence always?—Yes, I do not mind about that.

9877. But otherwise you would say that we were equally in line with the Germans as regards operations?—I do not think we can say that our restrictions have interfered, but if they were made any more strict than they are I have no doubt that they would.

9878. You think that would be a distinct disadvantage to us?—A distinct disadvantage.

9879. And you could not for one moment entertain the idea of leaving out of experiments which are allowed to be made, animals such as dogs, cats, or horses?—Or monkeys, certainly not.

9880. You think they are absolutely necessary?—I do.

9881. (*Sir Mackenzie Chalmers.*) I have not many questions to ask you. Your evidence here to-day represents, I understand, the practically unanimous opinion of your Council?—Yes.

9882. And going outside your Council, among the Fellows is there any minority, or a considerable minority, opposed to experiments on animals?—I am not acquainted amongst our Fellows with any views contrary to experiments on animals, except those of Sir Thornley Stoker upon one particular point.

9883. Those are demonstration experiments?—Yes.

9884. But we want to get evidence on both sides, of course, and I was wondering whether you could suggest to us any eminent Fellow who would give evidence on the other side?—I do not know of any of our Fellows who could give you any evidence of that sort.

9885. Practically, then, your evidence is the unanimous opinion of the Council and the unanimous opinion of the Fellows of the Royal College?—So far as I know it, and I think I would have heard if there had been any other view.

9886. Sir Thornley Stoker confines his objection to doubting the necessity of experiments before students as part of their general training?—Yes.

9887. Was he the dissentient that you referred to?—Not if you mean the gentleman who I said I thought had changed his mind. I said that there was one member of the Council (Sir Thornley Stoker is not now a member of the Council) who rather inclined to Sir Thornley Stoker's view at one time, but that I believed he now holds that opinion no longer.

9888. Now, then, as regards the point where you suggest an amendment of the law, you suggest that students who are about to become practising surgeons should be allowed to acquire manual skill by experiments on animals?—Yes.

9889. Would it satisfy your requirements if the animal was anæsthetised and then killed before it recovered from the anæsthesia, or would you require the animal to be allowed to recover?—It would not be desirable to let the animal recover in every case. For instance, if a surgeon wished to try some new method of suturing when a portion of the intestine had been excised, and he wished to see whether it was a good form of suture, and in many other cases. I simply give that as an example. There must be plenty of other operations where it is necessary that the animal should be allowed to live and should not be killed until an interval had taken place, in order to see what the actual result had been in the method of healing.

Mr. (now *Sir*) *H. R. Swanzy*, P.R.C.S (Ireland).

12 June 1907.

9890. That, if I may say so, would be a scientific experiment and not an experiment for the purpose of acquiring manual skill. As regards a young surgeon acquiring manual skill, would it satisfy your requirements if the animal were anæsthetised and killed before it recovered consciousness?—I presume that it would; but, really, that is a question which would, perhaps, be better addressed to a general surgeon.

9891. However, so far as you know, it would be sufficient?—Yes, so far as I know.

9892. I suppose eye surgery requires very delicate manual operation?—Yes.

9893. May I ask this question: Does skill become progressive?—Yes.

9894. One of the witnesses told us—I will not ask you if you agree with him—that before an ophthalmic surgeon became a really good surgeon he had to destroy a hatful of human eyes?—That is not an original saying of his; I fancy it was Dr. Mackenzie, of Glasgow, who said that long ago. But it is not true, of course.

9895. But there is still this element of truth in it, that a man's skill is progressive?—Yes.

9896. Do you think that a student, by operating on an anæsthetised animal which was killed before it recovered from the anæsthesia, would acquire skill in operating on the eye?—No, I do not. I do not think, with regard to the eye, there would be anything gained. I am not aware of any operation upon the eye, except the transplantation of the cornea, that I can think of where it would be of any advantage to the student or of an ophthalmic surgeon to operate on a living animal's eye.

9897. You think that he had better begin straight away on the human subject?—No, not straight away, but he can operate upon dead eyes. But I do not think that anything would be gained by operating on a living animal's eye. I think the operations I spoke of are those of general surgery, and more particularly those upon the intestines.

9898. How far are diseases of the eye common to human beings and to animals?—I am told by Professor Mettam, of Dublin, who is head of the Veterinary College there, that all the diseases of the human eye, except certain infectious diseases peculiar to man, also affect the eyes of animals.

9899. You have a common run of disease between animals and human beings?—Very much, it seems.

9900. I ask the question, because it has been suggested to us by certain witnesses that experiments upon animals are useless, inasmuch as an animal is so different from a human being that you can draw no useful inference. You do not agree with that statement?—I do not. One of the diseases that I have spoken of at considerable length here—glaucoma—is not at all uncommon in animals—especially horses are very liable to it; I have seen a horse myself with glaucoma, and I have used eserin for it, because it was in great pain, and relieved its pain in a few hours.

9901. Has iridectomy ever been performed upon a horse?—I do not know. I think if a horse is blind of an eye it is hardly worth doing any operation upon it except removing it. That is mostly what the veterinary surgeons do. A blind eye in a horse, or a nearly blind eye, is of no use.

9902. Horses suffer from cataract, of course?—Yes.

9903. Have we obtained any information, from observations on horses or experiments on horses, with regard to cataract?—I do not think we have.

9904. Is transplantation of the cornea a recognised operation now?—It is, but it is not very often done, because the cases where it suits are not very frequent. It is still in the developmental stage. We hope after a time to be able to use it more extensively.

9905. That, of course, does not come under the Vivisection Act; it is not done for the purpose of knowledge. It is a common operation on human

Mr. (now *Sir*) *H. R. Swanzy*, P.R.C.S. (Ireland).

12 June 1907.

beings?—Yes, but then the preliminary knowledge of it had to be gained. We could not do it on the human being until we had tried it on an animal.

9906. As regards what you were asked about yourself, I take it that your knowledge of the functions of the eye has been largely obtained by experiments on animals, and you apply that knowledge in practical surgery to the cure of human disease?—Yes.

9907. May I ask you, is trachoma a common disease?—Yes.

9908. What is the nature of trachoma? It is highly infectious, is it not?—It is very infectious; I would not like to say highly. It is a disease of the conjunctiva, the lining of the lids, and it is little bodies which form in the conjunctiva, called trachoma bodies, which destroy the particular spot in which they sit, and then the whole conjunctiva becomes destroyed and the cornea becomes opaque, too—through a growth on it called pannus—and it is for clearing the cornea that jequirity is used.

9909. Do animals suffer from trachoma?—I believe pigs do very much; I do not know about other animals; I understand that pigs do.

9910. Is it known what the source of the infection is in trachoma?—No, it is not; the micro-organism has not been found.

9911. Are there any experiments on animals at present being carried out with reference to the treatment and the source of trachoma?—I am not aware of them.

9912. Still, if it is a disease that animals can suffer from, information might be obtained, of course, from experiments on animals?—Yes.

9913. Do you operate chiefly under cocaine or under general anæsthetics?—Mostly with cocaine. I put drops of cocaine into the eye, and then the eye becomes anæsthetised, and you can operate without giving the person any pain.

9914. (*Mr. Tomkinson.*) That is a purely local anæsthetic?—Yes.

9915. That is quite effective, is it?—Yes, in cataract operations and iridectomy and such operations.

9916. (*Sir Mackenzie Chalmers.*) I only ask you for the purpose of a further question. In experiments on the eyes of animals it has been said by previous witnesses that the experiments are of a very painful character. But can the experiments which have been of use to you be carried out under cocaine; can the animal be anæsthetised?—The animal would require general anæsthesia; because it is not merely to do away with the pain, but it is also that it does not like to be restrained in any way. It is like a child. In many things that one has to do for a child one has to give general anæsthesia; whereas if you do the same thing for an adult, if you simply use local anæsthesia, the intelligent sense of a grown person will make him not resist. But a child will not be restrained, even to hold it without doing anything to it; it does not like it.

9917. Do you think that in experiments on animals cocaine ought to be allowed as an anæsthetic; or ought animals always to be put under general anæsthesia?—I would think that they ought to be put under general anæsthesia.

9918. Chloroform or ether?—Yes.

9919. (*Dr. Gaskell.*) I presume that in your student days, when you learnt physiology, there were practically no demonstrations, no experiments on animals at all?—I never saw them and never heard of them.

9920. So that naturally you would not have witnessed any in your student days?—I would not.

9921. There is one question I was wondering whether you could give us any information about—that was, with respect to certain experiments performed by Dr. Cecil Shaw for sympathetic ophthalmia. Do you know those experiments?—I know that he did perform some experiments some years ago, and they were published in the "British Medical Journal"; I think they were in connection with sympathetic ophthalmitis.

9922. They were?—I think he used jequirity in some way, jequirity beans.

9923. Were those done in Ireland?—They were done in Belfast.

9924. You had no personal knowledge of them?—I had not any except what anybody can read in the "British Medical Journal."

9925. I presume that experiments of that kind must necessarily be somewhat painful to the animal?—I certainly would suppose that they would be painful to the animal.

9926. In setting up inflammation in the eye and keeping the animal alive to see whether sympathetic ophthalmitis resulted?—Yes, it would be painful.

9927. Do you know whether the results were valuable?—No, I cannot say that I remember them well enough to say anything about that.

9928. Still, there can be no doubt that, even at the expense of some pain to the animal, it is well worth while, most important in fact, to find out the meaning of sympathetic ophthalmitis?—Most important indeed. Dr. Shaw desired by this means to find out whether or not the inflammatory process extended round by the optic nerve and commissure; but I forget now really what the result was.

9929. (*Mr. Tomkinson.*) I have hardly anything to ask you. In addition to what Colonel Lockwood asked you with regard to your qualification, as to the extent to which you subordinate the pain of the animal to the results derived from it, would you push that theory to an extreme in your opinion? For instance, supposing it was impossible to give an animal anæsthesia at all, would you place any limit upon the suffering which you thought it justifiable or right to inflict in order to promote research?—I think that the ascertaining of knowledge is to be put before the suffering of the animal; that is my own individual opinion. But I would always endeavour to the utmost to safeguard the animal from any pain, or even inconvenience, which could be avoided.

9930. So far as you know, that is practically the custom that is carried out so far as possible?—Yes, it is. In fact, so far as I know, animals do not suffer any pain during operations; and after operations which are done aseptically, as they all are, the animals also do not as a matter of practice and as a matter of fact suffer pain or inconvenience, I believe.

9931. I think that is very much the experience of human beings after a mere incision; that under aseptic and healthy conditions the healing up is accompanied by hardly any pain?—Yes.

9932. Have you any doubt in your own mind as to the possibility of keeping animals absolutely in a condition of insensibility for a prolonged period by anæsthetics?—I have no doubt in my own mind, because I know it on good authority; but I have no experience of my own to tell you.

9933. I think you have witnessed very few experiments on animals?—Yes.

9934. Is that from choice?—Not at all.

9935. Would you have any shrinking from it?—Not the slightest—no more shrinking would I have from seeing an animal operated on or experimented upon than I would have in seeing an operation in the theatre of a hospital.

9936. Then you do not look upon it at all in the light of being a cold-blooded and cruel practice?—Not at all—by no means; certainly not, because it is necessary. It would be very different if I saw an animal being stoned by little boys out in the street; I should think that a very beastly thing to witness; but I see nothing at all to shrink from in scientific experiments, carefully carried out in a physiological laboratory, with every precaution for the animal and for the success of the experiment.

9937. (*Dr. Wilson.*) You said that experiments on animals had assisted largely in the cure, or treatment, I should say rather, of glaucoma?—Yes.

9938. Is that disease ever cured?—Yes, it is.

9939. Even if it is far advanced, can it be cured?—No; when it is far advanced, if you allow a certain time to go past, you cannot do anything for it.

9940. It is only in the early stages that it can be cured?—Only in certain rather early stages.

9941. In diagnosing tubercle of the eye, I think you said that it was of great value to be able to inject the aqueous humour from a suspected eye into the eye of an animal?—Yes, for the purpose of diagnosis.

9942. But it is believed, is it not, that the tubercle bacillus is the only infecting agency, that the tubercle bacillus must be in the aqueous humour which you inject into the eye?—Yes.

9943. Could it not be developed, as it is ordinarily, and diagnosis made without having recourse to that experiment?—I do not quite understand.

9944. I mean that the tubercle bacillus, for example, in the sputum, is developed in artificial media?—Yes.

9945. And the bacteriologists never resort, so far as I know, to inject it into the eye?—Yes.

9946. Why could not the same test be made with regard to the aqueous humour which you suspect?—Because experience shows that it is not always successful. The tubercle bacillus in tubercle of the eye is very often in a very attenuated form, and you cannot cultivate it in the same way as you do the more active bacillus which occurs in pulmonary tuberculosis.

9947. It cannot be diagnosed in the ordinary way?—Very often not. I do not mean to say always, but it is often so with what we call attenuated tuberculosis of the eye. Those are the cases where you are likely to have doubts sometimes.

9948. Now with regard to the transplantation of the cornea, is it not the case that only one single instance of cure has been recorded by Zirm in 1905?—That is a very recent case. Zirm has published that case very recently, but Von Hippel published two cases on the human eye.

9949. But these are the only recorded instances of success?—Yes, but they are quite sufficient to show that the thing can be done.

9950. But have not oculists tried the experiment very often on human eyes?—I do not think so, because the cases in which it is applicable at present are not many. That is probably the reason why there are so few cases. We hope to develop it as time goes on. We have made a considerable advance in it now.

9951. The eye, of course, is a very sensitive organ to pain?—Yes.

9952. Would not the insertion of foreign substances into the eye for experimental purposes be likely to produce a great deal of pain?—Yes, they would, as a rule.

9953. And, of course, in experimenting on animals, although for cutting operations cocaine or anæsthetics may be used in the first instance, they could not be used continuously while the animal was under observation?—No.

9954. So that the animal must be more or less in a suffering condition while under observation?—No doubt there would be suffering in many instances.

9955. Then with regard to antiseptics, I suppose you have to be very careful about the use of them in operations on the eye?—Yes.

9956. So that what was called Listerism, or antiseptic surgery, never applied really to those operations. You could not operate under the spray on the eye?—No, you could not.

9957. Did you take any part in that controversy about Listerism some 25 years ago?—I did not take any active part.

9958. But operations on the eye must all along have been aseptic operations to be successful, clean operations?—Yes. We used also at the beginning to use antiseptics at one time, but they were not satisfactory; and then when the aseptic system came more to the front we were delighted to be able to abandon the other method, because the lotions which were used were often deleterious to the eye in themselves.

9959. So that what is called aseptic surgery really was not the direct outcome of antiseptic surgery as introduced by Lord Lister?—I am not so sure about that.

9960. Did he not himself own that he was rather ashamed and, with rare candour, regret that he ever used the spray?—I am afraid those are questions it is better not to ask me so much about, for I am not quite so familiar with them as perhaps a general surgeon would be.

9961. I only want to show, if possible, that eye surgery all along had to be clean surgery to be successful, even before what is called the aseptic treatment came into vogue?—Yes.

Mr. (now *Sir*) *H. L. Swanzy*, P.R.C.S. (Ireland).

12 June 1907

9962. Of course, when you refer to serum treatment, you refer only to it in connection with eye diseases?—Yes, that is all I refer to, only in connection with eye diseases.

9963. You are not commissioned to go further?—I have a perfectly free hand; but I consider myself to be as a witness more useful when I speak of what I know in my own branch than of what you would learn better from somebody else.

9964. Is it your experience that tuberculin is valuable in cases of tuberculous eye disease?—Most distinctly. I have had a good deal of experience of it in that disease.

9965. And it is used sometimes for testing when you are not certain?—Yes, I used it so the other day.

9966. Injecting it into a patient?—Yes, I did it the other day.

9967. Has it not failed as a test with human beings; has it not been given up?—I know that it was very much out of repute for some time, but it is obviously coming back into use again now—used not quite in the way it was at first; and I know from my own knowledge and experience that for tubercle of the eye it is a most useful remedy.

9968. Then in referring to operations for acquiring skill as regards students, you refer to general surgical operations?—Yes, I do.

9969. You say they are of no value as regards eye operations?—I do not think that practically they will be of much use as regards eye operations.

9970. Then you do not agree with Professor Starling in that respect?—I do not think I can say that they would be of use in regard to eye operations.

9971. But would you go so far, then, as to advocate what is pursued in one or two colleges in America, that is to say, using dogs as patients for amputations and all other surgical operations, and treating them as patients—I mean, keeping them under observation after the operation?—I do not think that there should be any restriction upon the kind of operations that should be performed upon animals, if it is held by surgeons that they could gain skill in operating upon the human subject by that means.

9972. But would you advocate students being allowed to perform them?—If they can learn something from it towards operating upon their patients when they get their qualifications.

9973. For acquiring operative skill?—Yes. I believe, however, that the great gain would be in intestinal surgery more than what you mentioned just now, amputations, and things of that sort.

9974. (*Dr. Gaskell.*) Might I ask one question in connection with something you have just said? Do you distinguish different parts of the eye as to the amount of pain that is likely to be caused; are all parts of the eye equally sensitive to pain?—Oh, no.

9975. The vitreous humour, for example?—That would have none.

9976. The retina?—There is no pain.

9977. The internal chamber of the eye, unless enlarged by pressure?—The internal chamber of the eye is the vitreous humour, and it is not painful. There is no pain in the vitreous humour.

9978. Is not the pain in the eye mainly a question of the cornea and the conjunctiva?—The cornea and the conjunctiva; and the iris is very painful to be touched, and the ciliary body is very painful to be touched.

9979. (*Sir Mackenzie Chalmers.*) There is one question I forgot to ask you; have you any opinion upon this point—whether licences and certificates ought to be granted to physiologists who are not medical men? Have the Royal College any opinion upon that point?—I have not heard it spoken of.

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S., called in; and Examined.

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S.

12 June 1907.

9980. (*Chairman.*) You have been appointed by the Royal Society of Edinburgh as their representative?—Yes. I have also been appointed by the University of Edinburgh as their representative. I was not specially summoned to-day on behalf of the University of Edinburgh, but if it is convenient to the Commission, I can give evidence on behalf of the University of Edinburgh as well.

9981. To a certain extent, I suppose it covers the same ground?—Practically it covers the same ground.

9982. You have been kind enough to send us a print of what I take to be the message of the Royal Society of Edinburgh?—Yes.

9983. Could you give us just a short account of that Society. Is it a Society under Royal Charter, like the Royal Society of England?—I presume so. I do not know much about the history of the Society, but it is organised on exactly the same lines as the Royal Society in London.

9984. That is sufficient. Therefore it devotes itself to science generally, not to any particular science?—Yes, to science generally.

9985. And, amongst others, to physiology and pharmacology?—Amongst others to physiology, pharmacology, and the medical sciences generally.

9986. Has the body which requested you to come and give evidence a council?—Yes.

9987. Can you tell us what that council is; is it elected by the general members?—By the general members annually.

9988. How many are there on the council?—I cannot say positively. I should think about 15 or 20, including vice-presidents and the president.

9989. Are you a member of the council?—I am.

9990. Were you present at the meeting at which these views were drawn up?—I do not remember being present at the meeting.

9990A. Does this statement represent the unanimous view of the council?—I understand that there was no other opinion expressed at the meeting. I believe it represents the unanimous view of the council as the council was then present—of course, I cannot speak for every individual member; and it has been more than once before the council. Although I am not quite sure whether I was present at the first meeting of the council at which the subject was considered, I was a member of a sub-committee which was appointed to draw up this statement. I did not draw it up myself. I was not the convener of the committee, merely a member of it.

9991. As this represents the views of the Royal Society of Edinburgh, perhaps we had better take it as it is printed. Would you kindly read it?—"Statement by the representative appointed by the Royal Society of Edinburgh to appear before the Royal Commission on Vivisection.—The Royal Society of Edinburgh, being deeply interested in the advance of all branches of science, values the opportunity which has been given to it of expressing its views upon the important question which is at present being considered by the Royal Commission on Vivisection. From very early times the experimental method of investigation has been practised in physical and biological science, and it may be regarded as affording the most fruitful means of obtaining accurate information in both of these fields. In the latter department this method necessarily involves experiments on living organisms. The whole fabric of physiological knowledge rests on such experimentation, and those who are conversant with the general trend of physiological research, know that results of the highest importance to the welfare of mankind have thereby ensued. From the time of the discovery of the circulation of the blood to the recent brilliant results which have so greatly enhanced our acquaintance with the functions of the brain and nervous system, the history of this branch of science reveals a long list of remarkable discoveries achieved by this method of inquiry. The knowledge which has been thus acquired has had a material effect in procuring the cure of disease and the relief of suffering, and has thereby been the means of saving and prolonging innumerable lives. In the field of pathology, the advance which has been made by means of the experimental method has been no less striking. Within the last thirty years the methods of the physician and surgeon in combating disease have been completely revolutionised. It is now possible to attenuate and perhaps destroy the virulence of many of the deadly complaints which afflict mankind. A new science—bacteriology—has sprung into existence, largely through experimental effort, and a new light has been shed upon many departments of pathology which were formerly obscure. Tubercle, diphtheria, yellow fever, tetanus, hydrophobia, anthrax, malaria, sleeping sickness, typhoid fever, and other diseases," among which I would include Malta fever, Nagana, and plague, "are now better understood, and by aid of the information gained by experiments on animals, most of them can be successfully grappled with." "The relation of man to his surroundings has thus been modified, and he now enjoys a degree of immunity from many of the dangers by which he is surrounded. In the sciences of pharmacology and therapeutics no advance in accurate knowledge is possible without experiments on animals. The action of drugs must be first tested in them, and the physician is guided by the information which is thus obtained. The Society, while fully admitting that every care should be taken that in the prosecution of experiments on animals no unnecessary pain is inflicted, is, at the same time, of opinion that the imposition of any further restrictions would impede the progress of physiological and pathological research, and would be attended by serious results to the progress of medical science and to the well-being of the community at large. Further, the Society would strongly deprecate any attempt to draw a distinction between experiments which are designed for utilitarian purposes and those which appear to have a purely scientific object in view. The history of science shows that it is not possible to draw such a distinction, seeing that so many scientific discoveries, which at the time they were made appeared to possess no utilitarian value, have in the course of time proved to be but the beginning of lines of investigation which have led to the acquirement of knowledge of incalculable benefit to humanity."

9992. Those are the views which have been submitted to the Council and approved by them, I understand?—Yes.

9993. The Council consisting, I suppose, of gentlemen who may be said to be representative of a considerable number of sciences?—Of all departments of science.

9994. I see at the end they advert to the desirability in their opinion of allowing experiments for the purpose of what we call pure research as opposed to research in order to discover a remedy for a particular disease; but I should like to ask you a little further: have your Society expressed the opinion as to whether or not experiments on animals should be used for purposes of demonstration in lectures to students?—No, that is one of the points to which I referred when I drew your attention to the fact that I was here to represent both the University of Edinburgh and the Royal Society. I consider that evidence on this point would be better tendered on behalf of the University of Edinburgh.

9995. Then I will not ask you anything further about the Royal Society, because I understand that these are their views expressed, and as they are not specially a medical body the importance of their view, I think we should all be of opinion is, that it is the view of scientific men generally on the value of experiments?—Yes.

9996. And specially in this case?—Yes.

9997. Perhaps any other evidence which you have to give we may take as being given on behalf of the University of Edinburgh?—I think you may take it as being given also on behalf of the Council of the Royal Society, the greater part of it at least, because any other evidence I have to give is supplemental to their statement. I have been given more or less a free hand by the Royal Society to give evidence on their behalf.

9998. Are you yourself in practice in Edinburgh?—I do not practise medicine.

9999. As a physiologist?—Yes, I am Professor of Physiology in the University.

10000. And therefore the Royal Society of Edinburgh are perfectly well acquainted with your views?—Quite.

10001. And with the nature of your experiments and generally?—I think so. Most of the work which we do, or a large part of it, is brought before the Royal Society of Edinburgh, and is published in their Proceedings and Transactions. It is partly brought before the Royal Society of London, and published in their Proceedings and Transactions, and partly in other journals.

10002. Having told us that, and that you have a free hand from the University and practically from the Royal Society too, I might take the rest without speaking to you as a representative purely but as giving your own evidence?—Quite so.

10003. With regard to what I was asking you about, demonstration before students, do you yourself demonstrate before students?—Yes.

10004. Has it been your practice?—That has been always my practice.

10005. Has it been the practice in Edinburgh generally for the Professor of Physiology?—It has been the practice in Edinburgh ever since physiology was taught in Edinburgh, so far as I can ascertain. It was the practice of my predecessor, Professor Rutherford; it was my practice at University College, London, when I was Professor there, and it has been the practice at Edinburgh since I have been there.

10006. And I take it from that that you approve of the practice?—I not only approve of the practice, but I do not think it is possible to teach physiology properly without showing a certain number of experiments to students. I do not consider that students can properly appreciate the importance of certain branches of the subject unless they actually see experiments performed upon animals.

10007. Could you at all classify what those subjects are, whether there are any special kind of subjects that require it more than others?—Yes. One subject is the action of the heart, the effect of the action of the heart in maintaining the pressure of the blood and the effect of certain nerves in influencing the heart and in influencing the blood vessels. The mere reading or hearing about these effects is an absolutely different thing from seeing them. I can myself very well remember the influence that was produced upon my mind when I first had shown to me by an experiment the effect of stimulating the vagus nerve upon the heart.

10008. Was that in London University?—That was in University College, London, when I was an advanced student.

10009. Who was the Professor then?—The Professor was Professor Burdon Sanderson, who was then Professor there of Practical Physiology. I have noticed myself the great interest, the keen interest, which intelligent students take in these experiments; they are vividly impressed by them in a manner in which they could not be by any narration of the results. For example, while observing the heart in an animal, the animal being, of course, in a condition of complete anæsthesia and absolutely insensible to pain, if one stimulates the vagus nerve and sees the heart immediately stop, not in contraction but in absence of contraction, in inhibition, produces a profound impression upon the mind regarding the influence which nerves are capable of exerting upon the organs of the body. And so with regard to secretion if one has placed a cannula in the duct of a salivary gland and on stimulating a certain nerve observes the secretion pouring from the gland, the impressions which are caused and the interest which is aroused, are altogether out of proportion to the effect which is produced when a mere narration of the fact is made by a lecturer. Such facts are so strongly impressed upon the mind by observation that they are never forgotten; they remain as definite accumulations of knowledge in the mind of the student. There are a certain number of fundamental experiments which I hold that physiologists ought not to be deprived of, and which should always be exhibited to students. One of these I have just mentioned, the action of the vagus upon the heart. I would add the action of the sympathetic nerve upon the heart and blood vessels, and the action of the depressor nerve upon the central part of the nervous system which presides over the blood vessels. There are also, besides the experiments upon secretion, which I have already mentioned, which is due to Claude Bernard the remarkable experiments of Bayliss and Starling upon pancreatic secretion. These gentlemen have shown that the pancreas is capable of being stimulated to secretion by the injection into the vascular system of an extract from the mucous membrane of the intestine which contains the principle to which they have given the name of secretin. This principle, when it is injected into the blood vessels provokes an extraordinary flow of pancreatic juice, and they have shown without doubt that this is the natural mechanism for secretion of pancreatic juice in the body. The material is poured into the blood from the mucous membrane of the intestine, passes to the pancreas, and causes secretion of the pancreatic juice. Before their experiments we practically knew nothing of such chemical stimulation of glands, and they have opened up a whole vista of enquiry, and enabled us to take a much wider view of the subject of secretion than it was possible to take before. Then there is the subject of internal secretion. It is only within comparatively recent years that we have understood that certain organs in the body, the functions of which were previously unknown, have the property of passing into the blood substances which circulate in the blood to the different organs of the body, and which affect the nutrition of the body generally, or secreting glands, or the vascular system, or the nervous system. This subject of internal secretion is one of the very greatest importance. I know of no more striking experiment for demonstration than the very simple one of injecting into the blood vessels of an animal, in which the blood pressure is being taken, a small dose of an extract which is obtained from the supra-renal bodies. If a minute dose of a solution containing the active principle of the extract (not more than one part in 100,000, or less) is injected into the blood vessels of the animal it is seen that the blood pressure is sent up to an extraordinary height, the heart is stimulated to greatly increased activity, and a whole series of phenomena are produced which are due to the action of this drug upon the muscular and other systems in the body. Certain other internal secreting glands are also known to produce effects of a similar or slightly different nature. One of these has only quite recently been discovered; the influence which is exerted by extract of the pituitary body. The effect of this when injected into the blood vessels is, like that of the supra-renal, to cause a very marked contraction of the blood vessels generally, while it differs from that of the supra-renal in producing, not an accelerated action of the heart, but a steadying of the heart, a slower action of the heart, the force of which is, however, well maintained. And it has quite recently been found that, in addition to this action, the pituitary body has a specific effect upon the kidneys, so that if the kidneys are not at the moment secreting there may be an immediate and rapid secretion of urine. It is well known to surgeons that as the result either of the anæsthetic which is employed or of the surgical operation itself the kidneys often do for a time cease to secrete. Under these circumstances, if the kidneys in an animal are in this condition, the secretion being in abeyance, a small dose of this extract of the pituitary body produces an immediate and rapid secretion of urine. There can be very little doubt that this discovery will have an important influence in connection with the views which we hold regarding the secretion of urine, and in all probability will have an important influence upon the treatment of cases of suppression of urine. This is an experiment which can be shown with the greatest ease to a class, and upon an entirely anæsthetised animal; and I have myself noticed the impression that it produces in the minds of students who see it, an impression which cannot be produced by any amount of lecturing or display of diagrams. One other point I would specially mention as of importance for exhibition to men who are to be engaged in the practice of medicine and surgery, viz.:—the effect upon the movements of the body of stimulating certain parts of the brain. It is now well known in consequence of the experiments of Ferrier that when certain parts of the brain in monkeys are stimulated certain definite movements of the body are produced, and this discovery has had a far-reaching effect in moulding our views upon the functions of the brain. The original discovery was made by Fritsch and Hitzig in the dog. But it was owing to Ferrier's application of their methods to the monkey that physicians and surgeons have been enabled to apply to man results which have been obtained upon animals, because the conformation of the brain in the monkey, although

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S.

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S.

12 June 1907.

simpler than that of man, is essentially similar, whereas the conformation of the brain in the carnivora (as the dog and cat) is different, and one cannot say that such and such a part of the brain, such and such a convolution, or such and such a fissure, represents exactly another convolution or fissure in man. In the case of the monkey and the ape we can make that assertion with the utmost positiveness, and now that these experiments have been confirmed and largely added to by the experiments of Sherrington and Grünbaum upon the brain of the chimpanzee and ape generally, their importance in relation to the practice of surgery and medicine in man has come out even more decidedly. This is a class of experiment which also makes a vast impression upon the student; he sees that what he has been taught in the lectures is not a myth or a fable; that it is an absolute statement of fact; he sees that the brain can be played upon, as it were, much in the same way as a musical instrument can; that by stimulation of this part a movement of the eyes is produced, by stimulation of that part a movement of the mouth, by stimulation of another part a movement of the finger or thumb, or of the toes. He sees for himself that this is so, and when he afterwards comes across cases in his practice in which there are convulsions due to some irritation of the brain, beginning in this, that, or the other part of the body, he knows what part of the brain is likely to be affected. These experiments—there are not many of them—do not require a large number of animals, because the experiments upon the heart and blood pressure and the effects of extracts and of the excitation of certain nerves can be performed in a single animal. The experiments upon secretion can be performed on one or two animals, the experiments upon the brain can be performed upon a single animal. Although a large number of facts can be shown, a very small sacrifice of animals is required. I may say that I have never found that horror of these vivisectional experiments which has been asserted by many anti-vivisectionists. It is entirely absent.

10010. (*Colonel Lockwood.*) Among the students?—Among the students; it is entirely absent.

10011. (*Chairman.*) We have had some witnesses who have told us of the great horror that is excited, and others have said, at least one or two, that great levity is excited. What have you to say with regard to that latter assertion?—I was not aware that levity was alleged, except in the book the "Shambles of Science," but I did not myself take that seriously.

10012. I do not think any other witness has said so?—Levity would not be permitted, I may say at once, by any class of students.

10013. Have you seen any tendency to that in lectures that you have either given or attended?—Never. The students with whom I now have to deal, and those with whom I had to deal at University College, were for the most part serious students, most anxious to learn. I do not mean to allege that there is not amongst such a class of students a man here and there who is desirous of finding something humorous in anything that a lecturer may say; and there are even some lecturers who even occasionally raise a laugh, but never in connection with vivisectional experiments. Levity might be shown at a lecture, but at the actual experiment and at the results of the experiment levity is impossible. Nobody who knows the class of students who study in Edinburgh could suppose for a moment that this would be tolerated. There is a remarkable public feeling amongst the students in Edinburgh which makes itself felt in the conduct of the classes. If your class sees that you are desirous of teaching them and of showing them experiments which are intended to add to their knowledge and to elucidate the facts which you have been teaching them in your lectures, they are absolutely quiet, and there would be no difficulty whatever, certainly during these experiments, in hearing the proverbial pin drop.

10014. Has that been your experience in London as well as in Edinburgh?—That was always my experience in London, but my experience in London is not of so great importance, because the classes in London were small in number, and a small class can be more easily controlled; but when one is dealing with large classes such as we have in Edinburgh one cannot control each individual student.

10015. I asked the question about London specifically because these accusations of extreme levity were made with reference to London demonstrations?—I should think things must have altered very much since my time if that were possible, because I never found in my long experience at University College the least tendency to levity.

10016. Both as student and lecturer?—Both as student and lecturer. I have now been teaching physiology in one capacity or another for 37 years, and I have a very large experience of classes of physiology and a very large experience of demonstrations and experiments, and I have never in a single instance found that there was the least tendency to levity when an animal was under experimentation.

10017. (*Chairman.*) You had just finished what you were saying about demonstrations, but I wanted to ask you this question. I understand from your evidence on that point that you think demonstration is useful for the purpose of showing to students decided facts, facts which are ascertained?—Yes, fundamental ascertained facts.

10018. And entirely ascertained facts?—Yes, entirely ascertained facts.

10019. Not matters of research?—No.

10020. And that, in looking at it in that light, it is not necessary to repeat the operations on many animals?—I do not understand you, because all experiments that are shown to students are repeated.

10021. But at one lecture you would experiment upon one animal?—Yes.

10022. To show the particular action of a particular drug, we will say?—Yes.

10023. You would not repeat that before the students on a number of animals?—No.

10024. But only at another lecture where you had occasion to show the same demonstration?—Yes.

10025. There have been some suggestions made that a number of animals are used up and thrown aside and others produced. What do you say with regard to that suggestion?—That is contrary to fact. No doubt the number of animals used for demonstration varies in different institutions. I imagine that in some they use more animals than we do in Edinburgh, because it is possible in some places, where there are fewer to see the experiment, to show more things, for there are some things that the student must be very close indeed in order to see; whereas in Edinburgh, where we have a large number of students, we show experiments to an audience of from 80 to 100.

10026. Is demonstration, in your opinion, useful with an audience as large as that?—Yes, in a specially constructed theatre. Our theatre is constructed exactly like an operating theatre. An operating theatre is constructed with a very steep auditorium, where the audience stand and look immediately down upon the operating table.

10027. But how far would the furthest person be?—He would not be much further than the length of this room.

10028. Say 20 feet?—The length of this room is a little more than 20 feet, I think.

10029. Say 30 feet?—I could give you the dimensions of the theatre,* but at any rate it has been arranged like an operating theatre, so that every member in the auditorum should be able to see most things. But in addition to that my practice is to allow the audience to file past. If, for example, the experiment is on the action of the heart or the pressure of the blood, and is going on continuously, they file past afterwards so as to be quite sure that they see the details of the experiment.

10030. But you could not, surely, at a distance of 30 feet, get any very useful idea as to whether certain secretion was being distilled from a certain vessel?—Yes, certainly, you can see the dropping quite easily; and the dropping is further recorded—there are special means of recording the falling of drops. The drop falls upon a lever, which effects electrical contact, and this moves another lever, so that the audience can not only see the dropping fluid, but can see its record on the smoked paper which is being moved along by clockwork. All this can be seen quite well in my demonstration theatre.

10031. Then there is another matter that I want to

* *The distance from the furthest bench to the operating table is 15 feet.* *E. A. Schäfer.*

ask you about. What do you say to the claim that is made by some, that experiments should be permitted for the purpose of gaining skill in operation?—I think that is rather a question for the surgeon than for the physiologist. I am speaking as a teacher of surgeons, but not as teaching them surgery.

10032. But still you are able to form an opinion?—Yes, I have formed a very decided opinion that it is in the highest degree desirable that any new operation should, if possible, be performed upon a suitable animal. For example, I know quite well that the eminence of Sir Victor Horsley as a brain surgeon has directly arisen from the experiments which he performed upon the brains of monkeys at University College many years ago. He would be the first to acknowledge that his reputation as an expert on that branch of the subject has arisen from such experiments. And obviously it would be an improper thing to attempt a new operation upon, say, the human intestine, without having tested the operation upon animals. I cannot conceive of this not being done. It would only mean the sacrifice of patients. I understand that the present law forbids it, and I am surprised that it is so. I had forgotten that that was the law myself, although I have studied the Act; I think that that portion of the law ought to be repealed. I suppose it was not contemplated in those days that such operations as are performed nowadays would be possible.

10033. What sort of operations do you think this sort of practice would be necessary or useful in, because the last witness, whose speciality was eye disease, seemed to think you would gain nothing for the purposes of operation on the eye from studying from the living object?—I am not able to say anything about the eye, because I am not an expert upon the subject, but I should have thought otherwise from general considerations; at any rate, I would rather myself not be operated upon by anybody who had not previously operated upon the eye in either animals or men?—I would not like to be the first person practised upon.

10034. Upon a living animal?—I would rather that the individual had operated upon other men.

10035. Everybody must take their chance of that; but I was speaking about a man beginning to practice operations on mankind without having previously experimented upon animals. The last witness said, I think, that in the matter of the eye, experiment on living animals was not an essential thing?—I really do not know. I suppose he has tried it himself. I suppose you asked him that question.

(*Sir Mackenzie Chalmers.*) He had not done it himself.

10036. (*Chairman.*) No, he said that he had not?—I cannot conceive, if the operation is done in precisely the same way, that an amount of knowledge might not be got from operation on living animals which could otherwise only be acquired by operating on man.

10037. But it would involve an immensity of practice upon animals if it is necessary, because I suppose you would say that a surgeon ought to experiment upon animals to acquire skill for every operation he would be likely to be called upon to perform?—I do not think so at all. I should not think so for amputation, for example, for one moment.

10038. Because amputating a rabbit's leg is not much use for amputating a man's leg?—No.

10039. But I was speaking rather of internal operations?—For such an operation, as in resection of a portion of the intestine, I do not think it is necessary nowadays to operate first upon animals, simply because the methods of operation have been so perfected, that anyone who has assisted in an operation will probably be able to do it perfectly well afterwards himself.

10040. What class of operation are you speaking of particularly?—I am speaking of any new kind of operation. Supposing, for example, no resections of intestines had ever been done before, then it would be absolutely necessary to try the experiment, first of all, upon an animal. It was done, of course, first upon an animal.

10041. But supposing that by vivisection of animals it had been ascertained that a particular operation might safely be performed in a certain way upon the human frame, what would you say then?—I do not think it would be necessary then to make experiments on animals in order to acquire manual skill.

10042. That meets very much what you say?—I do not think that it would be necessary.

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S. 12 June 1907.

10043. You are speaking about a man who is going to perform for the first time a particular operation—not necessarily limited to the very first time, but practically an entirely new operation upon mankind?—Yes, who has thought out a new method.

10044. Without having tried it upon an animal?—Yes, who has thought out a new method and wishes to apply it to mankind; but he does not know for certain what the result may be.

10045. But that confined it very much to a question of vivisection of animals simply for the purpose of acquiring knowledge?—Yes, it does amount to that.

10046. It is not operations for the purpose of acquiring manual dexterity?—The operations with that object, which I would have suggested myself as useful, would be eye operations; if eye experts think otherwise, I would not put my opinion against theirs.

10047. Then I only want myself to ask you one further question, and that is as regards anæsthetics. You have had, of course, very large experience in experiments upon animals which come under this Act, which requires complete anæsthesia?—Yes.

10048. I should like your opinion as regards both your own experiments and any experiments that you have seen performed by others, as to whether or not complete anæsthesia is always secured?—In all experiments which come under licence, complete anæsthesia is secured during the whole period of the experiment, however many hours it lasts.

10049. It has been suggested that complete anæsthesia may be obtained at first, but that animals are occasionally allowed to get out of that state of anæsthesia, and that if any more is applied it is too late, and after the animals have shown marked signs of pain by struggling, and so forth. What is your observation upon that?—That is not my experience at all. I do not mean to say that an animal will never make a movement when it is under anæsthetics; of course an animal will as a man will. But the object of the experimenter is to keep the animal under anæsthesia; his objects are likely to be entirely frustrated if the animal moves; and although the condition of anæsthesia may be more or less complete the amount of anæsthesia used in physiological laboratories is in almost every case vastly deeper than that which is used in the operating theatre. It does not matter very much to us whether the animal dies of anæsthesia or not; we lose our time only.

10049A. It has to die before it comes to?—Yes, but it does not matter to us very much, and we are much more inclined to push the anæsthetic because it is of the utmost importance that there should be no movements whatever, inasmuch as the least movement of the animal will entirely upset the delicate apparatus that we have to use. And the suggestion that we knowingly, or even unknowingly, allow the animal to come out of the anæsthesia is, on the face of it, an absurd suggestion, because it would absolutely defeat the object of our experiment.

10050. Have you observed in any operations that you have seen performed, either when you were a student or afterwards, any indifference or carelessness on the part of operators as regards anæsthetics?—I have never observed it. And I would not confine that answer to this country. I have witnessed a great many operations, in Germany and other countries, and the statements which fly about regarding the callousness of foreign physiologists to the sufferings of animals are wild, and quite unconfirmed by anything which I have seen. I myself worked for three months in Professor Ludwig's laboratory at Leipsic, where Dr. Gaskell was also working at the same time, and the system of anæsthesia employed was a very delicate one indeed, and had the result of rendering the animal absolutely quiescent during the whole of the experiment.

10051. That is in a country where it was not compulsory by statute?—That is in a country where it was not compulsory, and a country which has been specially vilified with regard to this subject. And I have seen at congresses of physiologists large numbers of operations performed, always under full anæsthesia. So that I think statements of that sort must be received very carefully indeed. There was a time no doubt, before anæsthesia was fully admitted, when surgeons in this country ridiculed the idea of

Mr. *E. A. Schäfer*, LL.D., SC.D., F.R.S.

12 June 1907.

anæsthesia and for some time refused to employ it. There may have been a reminiscence of that in early experiments, but that is long before my time. Within the period covered by this Act, I may say that I have never seen any operation performed without anæsthesia. Of course, I have seen operations in which the animals have been allowed to recover, and then the anæsthesia has passed off; but the actual operation I have never seen conducted without an anæsthetic.

10052. Are you speaking of this country?—I am speaking now of this country. I am also speaking of other countries.

10053. But assuming that in this country an anæsthetic has always been applied, the suggestion rather is, that it has not been applied fully and carefully, and so as to ensure complete insensibility to pain?—That suggestion has no grain of foundation.

10054. (*Dr. Wilson.*) May I take it generally that the same kind of experiments are resorted to to demonstrate your lectures as have been described to the Commission by Professor Starling?—I think generally, yes. I do not think I show quite as many as Professor Starling does, for the reason that I have mentioned.

10055. You use, of course, a large number of frogs for demonstrations?—Almost all our frogs are killed before we use them. I do not think that frogs are ever used which are not killed.

10056. The question has been raised, and I wish to put a few questions to you on the subject. You never, of course, submit any frog to an anæsthetic apart from the insensibility which is secured by pithing as a rule?—No, I think not. I have chloroformed them, but as a matter of fact they are killed. I do not think we ever use frogs which are not killed.

10057. Would you kindly describe the kind of pithing to which you resort?—The actual meaning of the word pith is the destruction of the medulla oblongata. I believe that to be the original meaning of the word. A pithed ox, for instance, is an animal in which a stab has been made in the medulla oblongata and the animal drops dead because its respiratory centre is destroyed; but by a pithed frog we generally mean complete destruction of the brain and spinal cord.

10058. Of both the brain and the spinal cord?—Yes. If I were to tell my assistant to pith a frog I should expect him to destroy the brain and spinal cord.

10059. Do you illustrate the experiments relating to circulation on a live frog?—Yes, on a frog with the brain destroyed.

10060. I think you gave evidence before the previous Commission?—I did.

10060A. I have been looking up your evidence, and I think you said that "in experiments upon the heart and circulation, it would not in many instances be allowable to remove the brain, because the removal would cause too great a shock to the animal"?—That is a mistake.

10061. You would like to correct that now?—If it is necessary to correct it, because it is perfectly certain that you can observe all the phenomena of the heart in circulation, even if the brain is removed. Without a qualification it was an incorrect statement.

10062. I made a note that it is in answer to Question 3865?—It depends upon what you mean by the word "brain." I was there meaning the whole of the brain, including the medulla oblongata.

10063. But not the spinal cord?—The spinal cord of course must be left, and the medulla oblongata for some experiments upon the heart and circulation must be left, and this is reckoned a part of the brain by anatomists. In that answer I have not the slightest doubt that I intended to include the medulla oblongata, but in the general popular signification of the term "brain" we mean the cerebral hemispheres. The popular signification of the brain is the cerebrum; and that, of course, can be removed without influencing the circulation, but you cannot remove the medulla oblongata without influencing the circulation. I have not the slightest doubt that in that answer I intended the brain to be understood to include everything within the skull; in the anatomical sense it is right; in the popular sense it is wrong.

10064. Then you contend that mere decerebration without destruction of the medulla oblongata renders any experiment upon a frog painless?—Absolutely.

10065. That is a point which has been raised, and it is disputed. For instance, it is admitted that a frog can jump and swim, and even, it is said, after it has returned to fairly normal conditions, can breed when the season comes round, even if deprived of its brain?—I do not see at all why it should not. That does not mean that it could have any conscious sensation. I do not know of any authority which holds that an animal deprived of the cerebral hemispheres can have any conscious sensation.

10066. It merely leaves the question open?—Yes.

10067. I do not want to press the point, but you yourself honestly believe that if a frog is only decerebrated it is deprived of all feeling?—I do.

10068. Now with regard to experiments on the larger animals. You of course have to use a good many dogs and cats?—Yes, in some experiments.

10069. Have you any doubt or difficulty at all in being able to conscientiously comply with the provisions of the Act, when you are carrying out even the most prolonged and severe operations before your students?—With anæsthetics, do you mean?

10070. Yes?—None whatever.

10071. You can always make sure?—Quite.

10071A. Would you be prepared to certify, on your soul and conscience, as they say in Scotland, that all experiments carried out on dogs, cats, rabbits, and other animals before your class are carried out to the best of your endeavour and belief, painlessly?—Yes, I would, certainly.

10072. It was stated by Professor Starling that in operating upon dogs to demonstrate a lecture, opportunity was occasionally taken to teach students methods of restoring or reviving the animals when the heart ceases to beat on respiration cases?—In consequence of anæsthesia?

10073. Yes?—In consequence of an excess of anæsthetic?

10074. Yes—that opportunity was taken to demonstrate to the students how the animal might be brought to, as it were?—Yes.

10075. In administering chloroform to patients, when an impending danger of that sort is created, is not the anæsthetic stopped at once?—I should hope so.

10076. Regardless of all risk of pain?—As long as there is insensibility there cannot be any recovery of consciousness to pain.

10077. But the anæsthetic is stopped at once?—I presume so.

10078. So that in a contingency of that kind, when you are operating upon an animal, you could not positively say—you could not be certain that sensibility may not have returned, if you are bringing the animal to?—You are assuming that the anæsthetic has been pushed to an extent in which the animal is practically dead, the heart or respiration having stopped, and that we are endeavouring to resuscitate the animal after that?

10079. Yes?—Absolutely the first thing to do is to shut off the anæsthetic. The animal having already absorbed such a large amount of anæsthetic, what you have to do is to get rid of some of it from the system. You then perform artificial respiration until the animal begins to respire of its own accord, and the moment that it does that you stop the artificial respiration, you allow it again to inhale the chloroform and air, and you go on with the operation. The animal has begun to respire, but its consciousness has not returned.

10080. How can you be certain of that?—We test consciousness in animals or in man by touching the cornea; that is one of the most sensitive parts of the body; and if we find that there is no reaction after touching the cornea, no closure of the lid, we know that there is no conscious sensation.

10081. What would be the agent that you would use—adrenalin?—No, artificial respiration.

10082. But for injecting into the veins you have mentioned adrenalin?—Yes, but I do not think we would apply that in this case. I think we would simply trust to artificial respiration.

10083. I think in connection with Dr. Oliver you were the discoverer of adrenalin?—More or less.

10084. But this adrenalin which is derived from the supra-renal capsules has failed, has it not, as a cure

for disease of these capsules—Addison's disease, for instance?—I have no knowledge. Addison's disease is a complicated disease. I do not think it is confined always to the supra-renal capsules; it is often due to phthisis, which affects the supra-renal capsules; and I do not think you would expect under those circumstances the giving of adrenalin to be of any pronounced benefit, but it is not a subject that I am competent to speak about; it is a clinical subject.

10085. Do you often use curare in this class of demonstrations?—Never. I have not used curare at all for years. I have not been engaged in any experiments which require the use of curare.

10086. It is very difficult to obtain it, I believe?—I believe it is difficult.

10086a. Would it not be very difficult to decide as to the completeness of the anæsthesia if curare were used along with chloroform?—Not if you maintained the same dose of chloroform. If you give curare you always give chloroform through an apparatus which delivers the regulation dose—a certain amount of chloroform mixed with a certain amount of air.

10087. By means of a Woulff's bottle?—There are special apparatus constructed for that purpose. I have devised one myself (which I think is better than the Woulff's bottle) which shows on an index the proportion of chloroform and air. What we do is this: we first chloroform the animal in a box or under a bell jar, when it is deeply under chloroform we put a tube into the trachea. We then connect that tube with this apparatus and pump air into the lungs—air saturated with chloroform, and air without chloroform. We observe that that mixture is sufficient to entirely anæsthetise the animal and to prevent any reflex action on touching the cornea. Then we can go on indefinitely with that mixture. I do not use curare. I have for years conducted no experiments which required the use of curare—which required complete paralysis of the voluntary muscles. We go on indefinitely without altering the apparatus. The animal will be kept alive for an hour, two hours or three hours, as the case may be, and will not move, and therefore we know that if we did give curare the animal would be equally anæsthetised.

10088. But have you not found it sometimes rather difficult to use chloroform for dogs with safety?—I made a special series of investigations on the action of chloroform and on the way in which chloroform kills. Those experiments were made with Dr. H. J. Scharlieb, and were published in the Transactions of the Royal Society of Edinburgh a few years ago. We found that we could with perfect security give chloroform in certain proportions, and that we could even increase the proportion to what would otherwise be a dangerous extent, if in the first place we added to the chloroform a small amount of alcohol, and also if prior to the administration of the chloroform we gave a small dose, a very small dose, of atropin under the skin. The way in which chloroform kills, unless it is pushed to an extremely dangerous extent, to which no administrator would ever think of pushing it, is by its action upon the nervous centre for the vagus nerve. It causes a direct inhibition through the vagus of the heart, which inhibition is so powerful that the heart stops, and it is very difficult indeed to get the heart to beat again. That effect of chloroform can be entirely abolished by the prior administration of a small dose of atropin, and we have very strongly expressed the opinion that in every case of the administration of chloroform there should be a prior administration of atropin in this manner. Whether this will become the practice of the medical profession or not I do not know, but it is my invariable practice to administer, especially to dogs, a dose of atropin, so that if they should get an excess of anæsthesia they shall not be liable to be killed by it.

10089. I have here a copy of a report of the Suspended Animation Committee in which I see an experiment described on a mongrel setter?—On what page?

10090. It is page 16: "Tube tied into trachea"?—

10091. In that case was an anæsthetic being administered at all?—"Anæsthetised with chloroform; ¼ grain morphia also given hypodermically."

10092. "Tracheal tube occluded for 4 minutes 20 seconds"?—Yes.

10093. But during that time the anæsthetic could not be being delivered by your apparatus?—A much stronger anæsthetic was being administered to the animal during that time—carbon di-oxide.

10094. You were asphyxiating it?—Obviously. It was absolutely insensible, and under any circumstances it takes several minutes for an animal to recover from chloroform.

10095. Here is another experiment on page 17: "smooth retriever," which was "anæsthetised with chloroform but died whilst being put under"?—Yes.

10096. That was one of the accidents?—Yes.

10097. You do meet with those?—Yes. No atropin was used in these experiments, it would have invalidated the object of the experiments.

10098. Then on page 19, Experiment IV., a "Dalmatian female." "This animal died whilst being put under chloroform." That is stated, is it not?—Yes.

10099. Then at the bottom of the same page—Experiment V.—a fox terrier." "The animal took the anæsthetic very badly"?—Yes.

10100. I am noting these to show that it is very difficult in some cases with dogs to safely chloroform them?—That depends. In these cases it did not matter very much whether the animal got an overdose of chloroform or not, because if it did we would take another animal. Our great object was to have the animal very thoroughly anæsthetised, consequently we took no special precautions to prevent its being killed by the anæsthetic otherwise than observing it carefully and endeavouring not to give a dose which would actually kill it. But the great object was to have it anæsthetised as deeply as possible. And I should explain that the expression "The animal took the anæsthetic very badly" means that the anæsthetic rendered the respiration rapid and shallow, so that there was a fear of the animal dying, not that it was imperfectly anæsthetised; it was rather too much anæsthetised, and went over rather too quickly.

10101. For those experiments, of course, you had a special licence?—No, those were done under the ordinary licence.

10102. Then there is Experiment XXXII., on page 48, "Moderate-sized mongrel terrier, male." "In this case also, as in the last, no anæsthetic was administered"?—Yes.

10103. That was one of your drowning experiments?—Yes.

10104. I suppose that was one of the cases in which you acted under a special licence?—Yes under a special certificate. I should like to explain that. In this series of experiments which were undertaken in order to determine exactly what happens during death by drowning, all except two (and the total number, I think, was 36) were conducted under the influence of complete anæsthesia during the whole time of the experiment; but it was of the highest importance, that one could appraise the value of these experiments, to do a certain number of control experiments in order to observe whether, so far as could be determined, the phenomena would be the same without an anæsthetic as with an anæsthetic. I therefore got permission from the Home Secretary to do ten experiments without anæsthetics, and I did two of them. The results which were obtained with those two showed so conclusively that the anæsthetic did not invalidate the object of the experiment that I left the other eight experiments, and did not perform them at all; and these are the two to which I refer. In these two experiments the animals were simply drowned by being held under water and not allowed to recover at all; and the obvious phenomena, such as the pulse and respiration, were observed and a *post-mortem* examination was made in order to see whether the *post-mortem* conditions were the same when they were drowned without any anæsthetic as with an anæsthetic.

10105. Would you briefly describe your method of restoring, or resuscitation, as it is called?—I will with pleasure. It simply consists in laying the patient upon the floor or ground, kneeling by his side, placing your hands flat on the lower part of the back of the chest, and allowing your weight to fall upon the chest, so that the weight of your body presses the air out of the lungs. Then when you raise yourself the pressure of your body—the weight of your body, is removed, the resilience of the chest wall causes the chest to expand again, and air is drawn into the lungs. By repeating these movements a sufficient number of times per minute, from 12 to 15, you can completely respire a man, so that he will not feel any necessity

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S.

12 June 1907.

for performing respiration himself. This I have shown by an experiment which I performed upon a gentleman who was working in my laboratory upon snake poison. He was led to believe that if, in cases of snake poisoning, artificial respiration were performed for an hour or two, the poison might have opportunity of eliminating itself, and wished to know whether by this method one could maintain respiration for as long as an hour. He allowed me to perform artificial respiration upon him for a whole hour without himself at any time wishing to respire, or taking any active part whatever in respiration. This method of performing artificial respiration was entirely suggested by the results which I had obtained in resuscitating dogs which had been drowned. I found that with dogs, which also have a resilient bony cage like man, it was possible to perform artificial respiration, simply by squeezing the bony cage, and placing the animal in a prone position, so that all fluid would flow out from the mouth, which was allowed to be dependent. Simply pressing was sufficient to drive out the water and air which was in the lungs, and in the mouth, and then the resilience of the bony cage would cause the air to pass in again.

10106. But could you make fit comparisons between experiments on dogs and experiments on man with Sylvester's method, for example?—I have tried Sylvester's method, of course.

10107. With dogs and man?—Yes; and I found it was impossible by Sylvester's method, either with dogs or man, to maintain respiration. It is quite impossible for you to allow another person to apply Sylvester's method for any considerable time; you must breathe; you do not get enough air into the chest by this method. You cannot do all the complicated motions involved in Sylvester's method in the space of time which is required to effect the requisite exchange of air per minute. You cannot do it efficiently. I have repeatedly tried it upon individuals, and found that it was quite impossible by it to get them in such a condition that they had not a *besoin de respirer*—a desire to breathe—a necessity for breathing. That is not the case with this pressure method, applied in this way. There is, as you doubtless know, another pressure method—Dr. Howard's method. Dr. Howard was an American who applied pressure when the body is on the back; his is also an efficient method; but has certain dangers. One is that in applying the pressure to the ribs you are somewhat liable in old subjects to break the ribs; and, as a matter of fact, I have been told by a gentleman who was present at a demonstration by Dr. Howard upon an elderly man in Dublin, that he did actually break some ribs. Another danger in cases of drowning, which came out very strongly in these experiments on drowning dogs, is that in drowned persons the liver is enormously congested, it is much too full of blood, and extends far below the ribs, and, if you press upon this part of the abdomen and chest, you are liable to rupture the liver; this would be a serious danger in applying Howard's method to cases of drowning. The method which I have explained to you, in which the patient is placed upon his face and pressure is applied to the back, has been applied in three of four cases of drowning with success by my students; to whom we teach it now always as a regular part of the curriculum. Two of these occurred at the seaside; these were cases of apparent drowning during bathing. One case in particular, of which a student told me, was at Shanklin. One of his fellow bathers got into difficulties and sank, and was not pulled out for nearly ten minutes. This student immediately applied the method, and in a quarter of an hour the man was up and walking away. An unfortunate case occurred to my knowledge, in which the method was being applied by one of my students. There were slight signs of recovery—I do not say that the patient would have recovered, because there are sometimes slight signs of recovery which pass off. But a doctor who knew nothing about the improved method came up—he only knew Sylvester's method—he ordered the patient to be turned over, and then set to work with Sylvester's method, when the symptoms of recovery immediately disappeared.

10108. But have you tested Sylvester's method and your own method spiro metrically on man?—Yes.

10109. And your own method shows that there is a greater respiration?—Yes, it shows that there is a much greater respiration; neither Sylvester's method nor the Marshall Hall method gave as much air as we normally take in with ordinary respiration; whereas both the Howard method and my own method gave a sufficient amount. It was tested very carefully spiro metrically.

10110. And do you say that you could not have evolved your own method without experiments on dogs?—As a matter of fact, it was suggested in the course of these experiments. I would not say that I could not have evolved it without those experiments.

10111. Now, I want to ask you a few questions about those brain experiments to which you have referred. You have performed a great many experiments on monkeys, have you not?—Yes.

10112. And Sir Victor Horsley, of course, and Dr. Ferrier, in this country, besides a number of physiologists on the Continent, have performed experiments on brain localisation?—Yes, and there are a good many more in this country than you have mentioned. There are Professor Sherrington's experiments, for example.

10113. And Grünbaum's?—Yes, with Dr. Grünbaum they have been very suggestive; and Dr. Beevor's with Sir Victor Horsley.

10114. Have not many of the results been rather contradictory, and practically of very little value in brain surgery?—I should think not; but you must ask a brain surgeon about that. Sir Victor Horsley will give you the best evidence on that point. They are not contradictory, so far as animals are concerned; I will answer for that.

10115. Experimentation on animals has done nothing for insanity, for example. That is on the increase?—I am afraid it has not.

10116. Or epilepsy?—Probably not. You must apply to a clinicist; I do not know.

10117. Perhaps it is not within your knowledge, but I have a note here of a statement made by Dr. Ferrier, who said at the British Medical Association meeting in Edinburgh as recently as 1898—that was long after his own experiments were carried out?—Yes.

10118. "The treatment of intra-cranial tumour forms rather a melancholy chapter in therapeutics"?—You must ask somebody else about that.

10119. You do not know about it?—I know nothing about it.

10120. I have several other instances of the same kind here of which you personally have no knowledge?—Absolutely none.

10121. But as regards these investigations of yours, is it not of interest to you to see how they are applied?—It is of immense interest.

10122. But you have not really time to read?—Yes, I read; but I am no authority on the subject. I could not say anything either for or against a statement of that kind.

10123. Will you take it from me that at the same meeting Dr. Ferrier further said that only 7 per cent. of cranial tumours are capable of being surgically dealt with?—I will take anything you like from you; but it is no good asking me that sort of question; you must ask a surgeon, or a neurologist.

10124. You see all these experiments are constantly paraded as being of such immense value to humanity and to the profession in medical and surgical practice?—I cannot gauge their value, or their want of value, I am afraid.

10125. Well, with regard to the operations themselves on animals, is not even your own mapping out of brain functions disputed by other physiologists?—No, I think not—only on unimportant details.

10126. I will ask you this question. Is it not logical to infer that as there is such a wide difference in the size, conformation, and arrangement of convolutions and fissures between the brain even of a monkey and that of a man, that useful deductions as to localisation of the functions of the human brain, based on experiments on a monkey, must be liable to a considerable amount of error?—No, I think not; I think the analogy is fairly complete, as has been shown by cases in which the brain has been exposed in man. In such cases it has been repeatedly found that excitation of the same or the corresponding part of the brain in man to that which yields a certain result in a monkey will give the same result. That has been repeatedly shown in man.

10127. In all these experiments on monkeys the operations themselves are no doubt carried out painlessly, but, at the same time, a great deal of pain must be suffered afterwards when the animal is under observation?—There is no sign of it, absolutely none.

10128. But you cannot say that there is none?—I can only say that there is no sign of pain. The animal is in a perfectly normal condition, eats its food, and runs about the cage, except for such paralysis as we may have produced as the result of the operation. If there was any sign of pain we should immediately kill the animal; but we have never had occasion to do this since the introduction of antiseptic methods.

10129. Have not experiments on the brains of animals been carried out ever since the time of John Hunter, during the whole of last century?—And long before that. Experiments performed before the introduction of antiseptics may well have been painful.

10130. (*Sir Mackenzie Chalmers.*) By reason of the after results?—Yes, because inflammation was then possible. But there is no such thing now. There is no sign of inflammation when you experiment on the brain. The conditions are perfectly normal.

10131. (*Dr. Wilson.*) But you cannot say that there is no pain?—You can only say that there is no sign of pain, no sign of *malaise*, no sign of illness whatever. You would be surprised to see how well these animals are, and look.

10132. Do you still believe it is necessary to continue these experiments on animals?—When we come to that question you must understand that there is no finality in knowledge. Our knowledge is an ever-widening circle, and as it widens there are more points to investigate.

10133. But I am referring to useful knowledge applicable to medicine and surgery?—All knowledge is useful; but what shall be applicable to medicine or surgery we cannot at the moment say. Who would have thought that Pasteur's experiments upon fermentation would be applicable to medicine and surgery? Who would have thought that there was useful knowledge in them? And yet that has led to the whole of Listerism.

10134. No?—Yes, directly.

10135. No?—Yes. Pasteur's experiments on fermentation led directly to Listerism.

10136. But by Listerism I understand the use of the spray?—Nothing of the kind. That is a mere detail.

10137. Really. I have seen Lister operate, but he afterwards gave up the spray. That was entirely the method?—That is not Listerism.

10138. We will have that out with some other witness. But was not all aseptic surgery a revolt against Listerism? There was a revolt against Listerism you know?—But aseptic surgery is the most complete carrying out of Listerism.

10139. But Listerism is antiseptic surgery?—No, certainly not. The principle of Listerism is the elimination of micro-organisms; you can eliminate those by antisepsis or by asepsis.

10140. Well, I did go into that discussion at the time, and, as I understand Listerism, it was what was called antiseptic surgery?—You must ask a modern surgeon.

10141. But, you see, you make a strong statement?—Yes, and I am quite prepared to stand by everything that I say. My experience is derived from animals alone, but that experience is very extensive, and I have never seen any sign of pain in an animal which had been anæthetised during the operation, and treated either antiseptically or aseptically afterwards. There are certain parts of an animal that we would not treat antiseptically, because the antiseptic itself might be a source of irritation; but, as a general rule, it is safe to apply a certain amount of antiseptic to the outside of a wound, because it ensures, especially in animals in which one cannot cleanse the skin so thoroughly as we can in man, that there shall be no invasion of germs from the outside. But the principle is the same. The principle is the exclusion of germs. In one case you kill them, and in the other case you prevent their entrance, but the essential principle of Listerism is the exclusion of germs. There is no question about it, I should think.

10142. But did not Lord Lister use the spray to kill the germs?—Yes, because he thought that the germs were more universally present than they are. He thought that they were universally present in the air, and that he must exclude air which had not been treated with antiseptics. But he has himself long since recognised that that is not necessary.

10143. I will not press that question, then, further, as you do not pretend to be a surgeon?—But I do pretend to understand something about that subject, because I deal with it every day.

10144. But you do not seem to have read up the subject very closely. Have you even seen Lord Lister operating under the spray?—He does not operate at all now.

10145. Have you ever seen him operating under the spray?—No, I have never seen him operate at all. I have operated myself under the spray, but I do not operate under the spray now.

10146. Was there not a revolt against Listerism, as it was called?—It was falsely called Listerism, if it was so called.

10147. No, it was called Listerism—the use of the spray, the use of antiseptic dressings and antiseptic ligatures. All that was included under the term Listerism?—Ligatures were not necessarily antiseptic. They were treated by antiseptics, but they were aseptic ligatures. But Listerism is the exclusion of germs from wounds. That is how I should define Listerism. How do you define Listerism? I am not examining you, I admit; but still, as part of the discussion you ought to tell me how you define it.

10148. I define it as I was taught. Killing germs in the air is Listerism.

10149. But was there, then, no revolt against Listerism?—No.

10150. But the revolt against Listerism was carried on by surgeons, who operated on the peritoneum?—I would not call it a revolt against Listerism; I would call it a modification of the method.

10151. I will not press this question further; I will get it out of someone else?—I would certainly rather that you asked a surgeon.

10152. (*Dr. Gaskell.*) Have you found that by giving atropin with chloroform you have always been successful?—Do you mean to say that it is impossible to kill the animal?

10153. I mean have you ever had any deaths?—Not with careful administration. Without atropin, with the most careful attention you may have deaths.

10154. Is that method of giving atropin more or less confined to your laboratories, or is it used elsewhere?—I think it is chiefly confined to our laboratories.

10155. You gave us a number of experiments that you advocated for students. Do I correctly understand that that included all that were advisable, or only samples?—Those are samples. I think other experiments might be shown, those are some fundamental experiments which I jotted down just before I came here.

10156. I noticed that you made no mention of respiration experiments?—One naturally shows respiration experiments along with the others. When you investigate the action of the vagus upon the heart you record its action upon respiration at the same time. I did not mention respiration experiments, I admit.

10157. I meant rather Hering and Breuer's experiment?—I am not in the habit of showing that.

10158. You do not consider it important?—I consider it important, certainly, but as a matter of fact I am not in the habit of showing it.

10159. Do you consider that the demonstrations that you do at Edinburgh are more or are less than what are done in other places?—I think they are rather less, because we have so large a number of students to deal with that as it is we are compelled to divide our classes for demonstrations into four batches, and we are compelled to repeat the same experiment four times.

10160. Have you read "The Shambles of Science"?—Yes.

10161. Have you noticed the nature of the demonstrations given there?—Yes.

10162. In your opinion were those justifiable?—Which are you referring to?

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S.

2 June 1907.

10163. All those quoted in "The Shambles of Science." Perhaps you do not remember them?—I am afraid not. Do you mean to say exactly as they are described?

10164. No; I mean the kind of experiment, the object of the experiment. There were experiments, of course, for advanced students?—Yes, they were experiments for advanced students. I may say that my experiments are none of them for advanced students. My experiments are experiments to the whole class. All students come to them.

10165. (*Sir Mackenzie Chalmers.*) Of what year?—They come to them in their second year.

10166. (*Dr. Gaskell.*) Do you give another course for advanced students?—We give a course to advanced students, but they do not have demonstrations in that course.

10167. Not special demonstrations?—Not special demonstrations; they come to the others.*

10168. In your time at University College was such a course for advanced students ever given as is described in "The Shambles of Science," or is that an innovation?—I think it is an innovation. There was not such a complete course given for advanced students in my time.

10169. Do you think it is a good innovation?—A very good innovation.

10170. Do you think that more care ought to be taken as to finding out the status of students before they go to those demonstrations?—I do not quite understand what care is taken there. It seems to me, from what I have read and what came out in the case of Bayliss *v.* Coleridge, that reasonable care was taken that the students should be *bonâ-fide* students and should be advanced students. They were recommended by the teachers in their respective schools. The University of London is quite different now from what it was when I was there. They now admit students from all schools to certain demonstration lectures. In my time, only my own students, every one of whom I knew, came to the demonstrations.

10171. I should rather like to know from you whether you would advocate any change in the law as it is at present administered or stated in the Act?—Perhaps I may read a statement with regard to that.

10172. I should like you very much to make a statement, because I hoped that I should have heard one already?—The statement is this. Although the Act has not been without benefit, because it has given to all intelligent laymen a definite assurance that no wanton cruelties (such as were basely insinuated before the system of licensing and inspection was instituted) are possible, and the reports have shown that all experiments are carried out with the least possible amount of pain, and in 99 out of 100 cases are absolutely painless from beginning to end—it must be admitted that it somewhat tends to hamper research. There is often too great a delay in the allowing of certificates, and by the time the inhibition to use them is removed (the normal period of inhibition being one week according to the Act, and the actual period of detention being often very much longer, at the discretion of the Secretary of State), the best opportunity for conducting the experiments may have lapsed. It was quite clearly the intention of the Act that all certificates should be granted by two eminent medical or scientific authorities, and although power was taken to disallow or suspend a certificate which had been granted, nevertheless this was obviously intended only to be used in case of any abuse or infringement of the Act. The Act nowhere gives power to the Secretary of State to impose any conditions on the certificates, but this power has been illegally assumed by successive Secretaries, and certificates are thereby materially modified and their usefulness seriously impaired. I would like to give an instance of that which occurred to myself. I mentioned two experiments which I performed on animals in connection with the subject of drowning. I asked for permission to perform certain experiments without general anæsthesia, because I was anxious to determine whether every condition was exactly the same without anæsthesia as with anæsthesia; accordingly I asked for permission to put a cannula into the artery of a dog's leg with complete local anæsthesia—cocaine, and during the drowning to make an experiment upon the blood pressure in that dog. I obtained a certificate for that purpose, but there was written over that certificate, "The preliminary operation which is suggested under local anæsthesia is hereby disallowed." (or words to that effect.) I consider that that was an illegal action on the part of the Secretary of State, but I had no remedy because the Secretary of State would simply have disallowed the certificate altogether, and I was compelled to do the best I could under the circumstances. This I put forward as an instance of a research, and an important research, being hampered by the authority of the Secretary of State acting, so far as I am able to ascertain, without expert advice, and, indeed, contrary to such advice. To enforce this illegal position the threat of suspension of the certificate is held over the head of the applicant. Further, all applications are referred, first, to the Association for the Advancement of Medicine by Research; and, secondly, to the Inspector under the Act. I do not object to a confidential reference to the Association for the Advancement of Medicine by Research, because that Association is composed of experts on the subject who are very capable of forming a judgment as to the expediency of proposed experiments, and their judgment can only have the effect of strengthening the position of the Secretary of State when he is called upon to decide on any doubtful question; nevertheless, it must be conceded that even this is clearly outside the four corners of the Act. On the other hand, the Inspector has to do with the administration of the Act, and is not necessarily an expert upon the subject of physiology or pathology or pharmacology; he has no special knowledge of what is or is not necessary for the advancement or knowledge in the special branches of these subjects; his duties are defined by the Act, and consist in visiting registered places for securing a compliance with the provisions of the Act. Personally, I have not a word to say against any advice which may have been given by the present or past inspectors in Great Britain; but the abuse of the position of the inspector has come out very glaringly in the evidence of the Inspector for Ireland, whose advice seems to have been acted upon for a time in opposition to that of the granters of certificates. I have studied the Act carefully, and I can find nothing in its provisions which warrants an appeal being made from the experts who are authorised to grant certificates to officials who are not experts in the science and are not conversant with the necessities of the investigation proposed to be employed. That is what I have to say about the present restrictions. I would strongly deprecate, on behalf both of the Royal Society of Edinburgh and of the University of Edinburgh, the imposition of any further restrictions whatever. Any restrictions on scientific work are detrimental to its progress, and further restrictions of experiments on animals might prove disastrous to the progress of physiology and medical science in this country. Since the revival of scientific medicine in the last two centuries we have taken a leading part in contributing to its progress. In no other country in the world is more regard paid to the ethical aspect of the treatment of animals, and the care which has always been exercised by physiologists in this country to prevent pain in the performance of experiments, is a reflection of a general sentiment which animates all class of society. (The callousness of the laity generally with regard to the sufferings which are inflicted upon animals intended for the table, or which are involved in pursuit of pleasure, is due, I believe, in the majority of cases, to sheer ignorance.) Nevertheless, I have not found any disregard of animal suffering to prevail amongst physiologists and medical men of other countries, in spite of the fact that in some countries the people generally are far more callous regarding animals than are we ourselves. It is strange that this should be the only country in the world in which restrictions are placed on the use of animals for the purpose of advancing medical and scientific knowledge, in spite of the fact that there is overwhelming evidence that the actual amount of pain inflicted is infinitesimal compared with the results achieved and compared with that which is daily and hourly inflicted in the pursuit of pleasure or of commerce. Even quite recently a clause was inserted in an Act of Parliament prohibiting stray and unclaimed dogs seized by the police being employed for the advancement of medical knowledge. The silliness of such a regulation is self apparent, for these animals are condemned to die, and are in many cases killed by a process of suffoca-

* *Mr. Schäfer subsequently wrote to say that he is informed by Dr. Sutherland Simpson, the University Lecturer on Experimental Physiology, that this year for the first time he has shown a single experiment on a rabbit, under Certificate C, to the advanced class of Experimental Physiology.*

tion; at the best they are killed by the same anæsthetic as would be employed in the laboratory; and the result is that other dogs have to be killed in the laboratory and the number of animals sacrificed is increased by so many. Who benefits by this? Certainly not the canine race.

The necessity of employing dogs has been emphasised by others who have given evidence, but it cannot be too strongly insisted upon. No other animals are available for experiments in important fields of physiology. Among these I would instance experiments upon the heart and circulation, upon the secreting glands and the digestive system, upon the kidneys and the formation of the constituents of urine, upon lymph formation, upon metabolism, and lastly experiments on the nervous system, in certain of which animals which can be trained must be employed. Dogs are the only animals which are available for many such experiments.

10173. Do not you think it would be a good plan if animals which are kept alive under Certificate B were not necessarily obliged to be kept in the laboratory in which they are operated upon; that they might go to a farm, for instance?—I was not sure that they were necessarily kept in the laboratory.

10174. We have understood so here; that they are obliged to be kept in a licensed place?—Certainly, if it is the case it is unnecessary and might be detrimental. As a matter of fact, I do not think I have understood that. I do not know whether I have infringed the Act myself in that respect.

10175. They have to be kept in a licensed place, I understand?—Supposing that a horse is being used for the preparation of serum?

10176. That does not come under it?—It might be done experimentally. Are you not to put it out to grass? It is nonsense.

10177. (*Sir Mackenzie Chalmers.*) There is a special form of certificate for that; the Board of Agriculture get special certificates.

10178. (*Dr. Gaskell.*) But the ordinary case is that the animals have to be kept in the laboratory, in a town very often, and it has been strongly advised by others that Certificate B should be altered in that respect. I wanted to know your opinion on that point?—There is no reason whatever for it. The new place would be registered.

10179. You naturally agree with that?—Yes.

10180. Would you also agree with this, which has been suggested to us: that in case of inoculations those inoculations should not necessarily be done by the licensee, but that authorised laboratory assistants should be allowed to do them?—I do not know. I think I should like to reserve my opinion on that. I have not thought about it. I would not allow my own laboratory assistants to do any experiment for me or to make any observations.

10181. I am only speaking of mere inoculations?—I would reserve my opinion.

10182. Many laboratory assistants are experienced in that respect?—Yes, of course. What you really mean is that laboratory assistants should be licensed?

10183. No, that was not the suggestion made to us. The suggestion made to us was that the licence to the professor should carry with it the power of the laboratory assistant to do a simple thing like an inoculation.

10184. (*Sir William Church.*) There are pathological researches at the present time going on in which perhaps 100 inoculations take place as quickly as possible?—Yes.

10185. At the present time it is a great infliction that the head, who is perhaps the only man who holds a licence in connection with that research, should have to spend all his time in making these 100 or 200 inoculations—pricks?—Yes, if that is what you mean I should certainly agree that that should be done, because a man who does that is acting simply as a machine.

10186. It has to be done by a man who holds the licence?—It has to be done under his sanction. I did not understand the question.

10187. (*Dr. Gaskell.*) I am sorry. That is all I meant. Would you be inclined to confine the Act to warm-blooded animals—a modification in that direction?—Yes, I should. I think it is absurd to suppose that cold-blooded animals feel in the same way that warm-blooded animals do. I do not see why it should not be so confined.

10188. I believe the Act originally was framed with those words?—Yes, it was so framed. Nobody who has observed fishes, for example, can possibly imagine for one moment that they feel pain in the same sense that warm-blooded animals do.

10189. Then there is one other question that I want just to have your opinion upon. Do you use morphia often in your laboratory?—No, I do not use morphia. I used to use it more often, but I use it less often now, because I use atropin, and they are somewhat antagonistic.

10190. Would you say that morphia only dulls pain and does not remove it?—Certainly not. A sufficient dose of morphia absolutely removes all signs of pain.

10191. (*Sir Mackenzie Chalmers.*) You yourself are a medical man, are you not?—I have a medical qualification. I am on the Medical Register.
